The conclusion having been reached that vitamin C is identical with hexuronic acid, it becomes of obvious importance in the first place to see how this can be reconciled with Zilva's contention[1] that there is a lack of parallelism between antiscorbutic activity and reducing capacity—one of the most characteristic properties of hexuronic acid. Fig. 1 summarises all the data given by Zilva, *mean* values for antiscorbutic potencies being plotted at each level of reducing capacity. Bearing in mind the unavoidable variation in biological response between individual experimental animals, it becomes evident that Zilva's data, once they are analysed in this way, appear in fact to afford good evidence of a close quantitative relation between reducing capacity and antiscorbutic activity in lemon juice fractions, and therefore are not at variance with the hypothesis that hexuronic acid and vitamin C are identical.

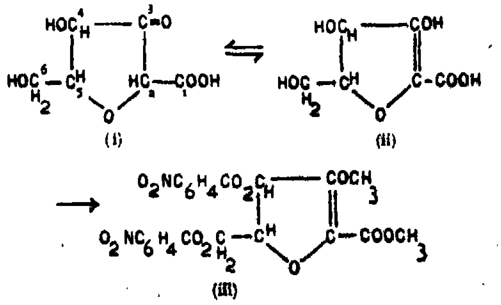
Constitution of Vitamin C

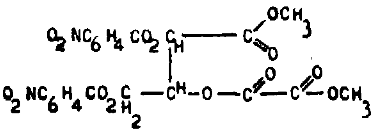
In our first communication[1] we proposed the formulation of vitamin C as a furane- or cyclopentane-derivative. In consideration of further investigations which we have made, we now consider the furane type of structure (i and ii) well established. This conclusion rests upon the following observations; neither the dimethylvitamin nor the di(nitrobenzoyl)-dimethylvitamin (iii) contains a carbonyl group. The



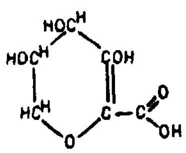
double bond in (iii), which does not react with bromine or with permanganate, is attacked by ozone to give a neutral product, melting point 162°, which does not react with ketone reagents. Its composition is

$C_6H_4O_3(OCH_3)_2(OCOC_6H_4NO_2)_2$. (Mol. wt. in camphor and in benzene.)

Since no reduction in the size of the molecule has occurred, the double bond must exist in a ring. Further, since neither carbonyl nor free carboxyl groups are produced, both the carbon atoms associated with the double bond must be attached to ether-linked oxygen atoms. The ozonisation product is thus formulated as (iv), as the methyl ester of a trihydroxybutyric acid, in which two of the hydroxyl groups are esterified with *p*-nitrobenzoic acid and the third with oxalic acid monomethylester.



(iv)



(v)

In agreement with this, five equivalents of alkali are used in its hydrolysis. The oxalic acid so produced was collected as calcium oxalate and after re-solution titrated with permanganate. The trihydroxybutyric acid is optically active, but its examination is not yet completed. The powerful reducing properties of the vitamin are related to the H–atom, attached to the C_2–atom, which may be readily oxidised to hydroxyl. Its replacement by CH_3, in the enol-form (ii), gives rise in the case of the dimethylvitamin, to a substance stable to oxidising agents. Since the oxidation product is a furanose derivative, its great reactivity is understandable. Besides the structure (i) (and ii), the structure (v), with its corresponding enol-form, may also be possible. In consideration, however, of the observations of Cox, Hirst and Reynolds[2] (production of *d*-threonic acid by permanganate oxidation; formation of furfurol) the formula (v) is excluded (it would yield erythronic acid, since the vitamin gives a monoacetone derivative). Since we have examined the constitution by the mildest chemical methods, secondary changes in this most reactive molecule are excluded. A detailed communication will appear elsewhere[3].

A Carotene Derivative giving with Antimony Trichloride an Absorption Band at 610–630 mμ.

CAROTENE and vitamin A share with a variety of polyene substances the property of giving a blue solution with antimony trichloride in chloroform. Spectroscopical research shows that carotene gives a specific absorption band with a maximum at 583–590 mμ, whereas vitamin A gives a maximum absorption band at 606–620 mμ with the antimony trichloride reagent.

It is very probable that carotene is converted into vitamin A in the body. Until now, it has not been possible to obtain this reaction *in vitro* by purely chemical treatment.

Recently we have obtained a carotene derivative with an absorption band at 610–630 mμ with the Carr and Price reagent. 150 mgm. of carotene (from carrots) is boiled under a reflux condenser for 15 minutes with a mixture of 100 c.c. of acetone and 1 c.c. of hydriodic acid (sp.gr. 1·7). After cooling to room temperature, 150 c.c. of petroleum ether is added and the acetone washed away with water. The petroleum ether solution is vigorously shaken up for some time with a strong sodium thiosulphate solution. With antimony trichloride in chloroform (with addition of one drop of acetic acid anhydride) a blue colour develops with absorption down to 640 mμ.

The petroleum ether solution, to which is added 20 c.c. of 1 per cent sulphuric acid, is shaken up with small quantities of a dilute (1 per cent) sodium nitrite solution, testing from time to time with the antimony trichloride reagent. A strong absorption band at 610–630 mμ appears. A product with maximum absorption is approximately reached when the colour of the petroleum ether solution has nearly disappeared.

Too much sodium nitrite causes a redder Carr and Price reaction, whereas the absorption at 610–630 mμ decreases.

The substance, although a derivative of carotene and giving the same absorption band as vitamin A, was found to be devoid of growth-promoting activity; small quantities of indol and the inhibitor of cod liver oil caused inhibition of the absorption band.

Induction by Coagulated Organisers in the Chick Embryo

IN a series of short communications, Bautzmann, Holtfreter, Spemann and Mangold[1] have recently reported the results of experiments in which they attempted to obtain typical organiser reactions (that is, the induction of a neural plate in the presumptive epidermis in *Triton*) by organisers which had been killed. Marx[2] had previously demonstrated that inductions could be performed by organisers which had been narcotised by trichlorbutyl alcohol to such an extent that they degenerated and were absorbed, while Spemann[3] had obtained inductions by organisers which had been crushed, but not by those which had been frozen or dried.

Holtfreter has been by far the most successful of the newer workers; he reports large and typical inductions by organisers dried at 60°C., or heated to 100°C., or frozen, acting upon either isolated pieces of presumptive epidermis or on the same tissue in its normal place in the embryo. Bautzmann describes two structures, induced by organisers which had been heated to about 60°C., which he is inclined to interpret, now that the possibility has been proved by Holtfreter, as atypical induced neural plates. Spemann has obtained one induction by an organiser killed in 96 per cent alcohol, and Mangold reports some doubtful cases which raise the possibility that the inducing agent can diffuse into agar blocks.

Since October 1931 I have been attempting to obtain inductions by dead organisers in the chick embryo, the organisers being killed either by heat or by acetone. But it was usually found that the dead implanted substance became enveloped by mesenchyme or endoderm cells from the host, and was thus insulated, as it were, from the host ectoderm, so that no inductional effect was obtained or could be expected. The insulation is least efficient in the comparatively mesoderm-free region near the head, but in this situation there is great danger of an induced neural plate becoming incorporated into the host's neural plate and therefore indistinguishable. Two fairly clear inductions have, however, been obtained in this region. In both cases the graft consisted of the anterior part of a chick primitive streak, and was coagulated by being placed, as dry as possible, in a thin-walled glass tube which was then dipped in rapidly boiling water for about 30 seconds.

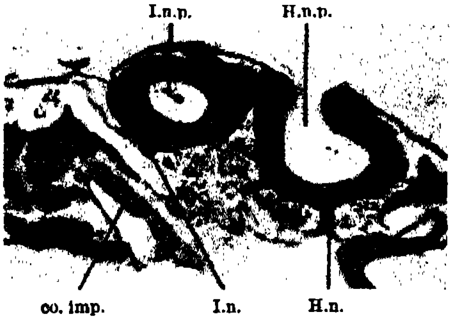

FIG. 1. Section through posterior part of induction. I.n.p., induced neural plate; H.n.p., host neural plate; I.n., induced notochord; H.n., host notochord; co. imp., coagulated implant.

This treatment left the tissue in a hard, almost horny condition: sections show that it has been completely coagulated, and not merely rendered necrotic. In one case the induced neural plate is united throughout its length with the host plate; the combined structure is very asymmetrical and in its folding shows clear indications that it consists of two parallel plates which have united laterally. In the second, and more diagrammatic case, the induced plate is again united with the host plate in the anterior region, but farther posteriorly, at the level of the hind-brain, it is quite separate and is accompanied by an induced notochord (Fig. 1). The presence of the induced notochord shows that we are not dealing, as Spemann concluded for the amphibian experiments, merely with the "Umschlag von präsumptiver Epidermis in Medullarsubstanz", but on the contrary, that the embryonic axes induced in this way may include several, perhaps all, of the axial organs: in fact, that the induced axis has its own "individuation field"[4]. From Holtfreter's account one would have thought that the same was true in the Amphibia.

Although it is perhaps not difficult to imagine the mere presence of a new individuation field being induced by a dead organiser, it is much more difficult to believe that dead material could determine the regional character of the induced field: and in the specimen described it probably has not done so. This is suggested by the fact that the induced notochord extends exactly as far towards the anterior as the host notochord, indicating that the induced axis owes its regional structure to the host. I have recently[4] argued that in normal inductions by living organisers the regional structure of the induced field is determined by the host and the graft working together. It would be very interesting to observe the regional character of neural plates induced by dead organisers near the edge of the area pellucida, where the host's influence is very small and can be overcome by that of a living graft; but as yet all dead grafts in such situations have become enveloped by cells from the endoderm.

Life-History of the Fowl Tapeworm, *Davainea proglottina*

IN 1888–92, Grassi and Rovelli[1] fed onchospheres of *Davainea proglottina* to the slugs *Limax cinereus*, *Agriolimax agrestis* and *Limax flavus* and were able in less than twenty days to obtain cysticercoids which when fed to hens developed into *D. proglottina*. In spite of these experiments, the authors did not exclude the possibility of direct infection, since they considered that these intermediate hosts were not present in sufficient numbers to account for the very heavy infection of the poultry in Rovellasca where they worked. Railliet and Lucet[2] attempted to establish direct infection and failed, but they considered that other slugs, in addition to those used by Grassi and Rovelli, could serve as intermediate hosts.

In Great Britain, Meggitt[3] attempted to repeat the experiments and fed onchospheres to the following slugs: *Arion ater*, *Arion hortensis*, *Arion circumscriptus* and *Agriolimax agrestis*. After intervals of 10–35 days the slugs were killed and examined but no cysticercoids were obtained. Meggitt did not consider the experiments conclusive since he experienced considerable difficulty in keeping the slugs alive in the laboratory. Later, Joyeux[4] in France and Bisset[5] in England again failed to establish *Agriolimax agrestis* as an intermediate host. In the United States, however, Chandler[6], by feeding proglottids to two specimens of *Agriolimax agrestis* and one of *Limax flavus* was able to obtain cysticercoids, and later Myrna Jones[7] successfully infected four species of terrestrial snails which are not indigenous to Great Britain.

Only one slug, *Agriolimax agrestis*, was used by all the authors and from their observations it was found to serve as an intermediate host in Italy and the United States but not in France and England. In view of this discrepancy, I proceeded in October 1932 to reinvestigate the life-history with relation to this slug and I have been able to obtain cysticercoids experimentally. Wetzel[8], who has apparently been working for some time on similar lines in Germany, has recently published an extensive paper on the life-history of *D. proglottina*, and I can confirm his observations on the active migration of the onchospheres through the wall of the alimentary canal of the slug and the subsequent development of the cysticercoids in the body cavity or digestive gland.

In view of the failure of previous experiments in Great Britain, a brief account of the technique adopted may be of interest. As I was unable to breed slugs in the laboratory during the autumn, some two hundred slugs were collected; half of them were examined and found to be free from infection. The remainder were used in equal numbers for controls and experiments. They were kept in batches of 10 in Petri dishes (4·5 in. in diameter) lined with damp filter paper. Although the slugs will feed on a variety of vegetable foods, in order to eliminate all possibility of outside infection, they were fed on the foliage cut from wheat grown on moist flannel in the laboratory. The Petri dishes were cleaned, and the filter paper and food were replaced daily.

Active ripe proglottids of *D. proglottina* were obtained from the duodenum immediately after an infected hen was killed. The proglottids were washed rapidly in tap water and then placed on the filter paper in the Petri dishes containing the experimental slugs. The slugs ate the proglottids with avidity and the process could be watched under a binocular dissecting microscope. Some of the slugs were kept at a room temperature of 16° C. and others were placed in the incubator at 24° C. At the former temperature cysticercoids developed in 21–22 days and at the latter in 12–13 days. By killing and examining some of the experimental slugs at varying intervals, the route of infection was established and all stages of the development up to and including the cysticercoids were obtained. At the conclusion of the experiments the control slugs were examined and found to be uninfected.

It does not follow that *Agriolimax agrestis* is the only intermediate host in Great Britain, and further experiments will probably confirm Wetzel's observations that in addition to this form and *Limax flavus*, the young stages of *Arion hortensis*, *Arion circumscriptus*, *Arion intermedius*, and *Cepea nemoralis* may serve as intermediate hosts.

Phytophthora megasperma causing Pink Rot of the Potato

DURING the course of an investigation into the occurrence and distribution of pink rot of the potato in Northern Ireland, a species of *Phytophthora* other than *P. erythroseptica*, the normal cause of the disease in the field, was isolated from tubers involved in an outbreak of the disease at Culnafay, County Antrim. Numerous isolations made between 1928 and 1932 from diseased tubers occurring in the same field at Culnafay have proved to be *P. erythroseptica*, the species referred to having been obtained on one occasion only. The isolation was made in January, 1930. A series of inoculation experiments has shown that this species causes a tuber rot of the potato indistinguishable from that caused by *P. erythroseptica*. The isolation was found to differ from *P. erythroseptica* mainly by the production of a preponderance of paragynous antheridia and in the large size of its oospores. We are grateful to Mr. Ashby of the Imperial Mycological Institute who has identified it as *P. megasperma* Drechsler.

P. megasperma was first recorded by Drechsler in 1931 as causing a crown rot of hollyhocks in the United States[1] and it would appear that this is the first record of its occurrence outside the United States. Although a number of species of *Phytophthora* will cause pink rot of the potato under conditions obtaining in the laboratory yet, in Northern Ireland, no species other than *P. erythroseptica*, to which must now be added *P. megasperma*, has been found as the cause of the disease in the field.

Snails and Changes in Sea-Level

IN NATURE of April 7, 1923, p. 464, I directed attention to the great changes in sea-level assumed by some geologists to have occurred during Pleistocene times. Reference was made to the small I. de Cima, close to Porto Santo, in the Madeira group. This islet has a very distinct species of snail, in great abundance, and if the postulated changes in sea-level actually occurred, it is hard to understand why the snail did not reach the main island, or, at another time, perhaps perish beneath the waves.

There has recently been published a still more striking example of a snail fauna on a small island, distinct from that on the adjacent larger island. Dr. A. Wetmore and Mr. F. C. Lincoln in 1931 visited Beata Island, which lies about six miles off Beata Point, the southern end of the island of Haiti. Beata Island is connected with Haiti by a submarine bank, on which there is 12–18 ft. of water. It is about four and a half miles long, and four wide. The U.S. Pilot gives an elevation of 330 ft. for Beata, but Wetmore and Lincoln estimated it to be about 75–100 ft. The island is of limestone, and much eroded.

A collection of land snails from Beata Island was submitted to Dr. P. Bartsch, of the U.S. National Museum, with the following astonishing result: *Chondropoma*: two new species, one representing a new subgenus; *Lucidella*: one new species; *Eutrochatella*: two new species; *Ceratodiscus*: one new species; *Cepolis*: two new species and a new subspecies; *Plagioptycha*: one new species; *Thysanophora*: two new species; *Urocoptis*: one new species; *Brachypodella*: one new species; *Macroceramus*: one new species; *Varicella*: one new species.

Thus the whole snail fauna is apparently peculiar to this small island, separated from the main island of Haiti by a channel said to be as shallow as 18 ft. Here is certainly a problem for the geologists.

Amplification of the Ionisation Produced by Radioactive Sources

VARIOUS devices have been described for employing thermionic valves to measure small current. In most of these, the necessary sensitivity is only obtained by using very sensitive galvanometers in the anode circuit of the amplifying valve, which magnify all irregularities due to faulty filament and anode batteries, as well as 'zero creep' effects due to leakage or accumulation of wall charges. Compensation for anode battery fluctuations can be eliminated by the 'valve bridge' method, but such an arrangement, whilst considerably complicating the circuits, only partly removes the causes of unsteadiness, so that a comparatively low limit of sensitivity is attainable, under steady conditions.

The electrometer valve, which has a grid filament resistance of the order 10^{15} ohms, provides a method of measuring ionisation effects, which seems superior to other valve methods so far described, and compares very favourably with the ordinary standard electrometer methods up to a sensitivity corresponding to 500 divisions per volt.

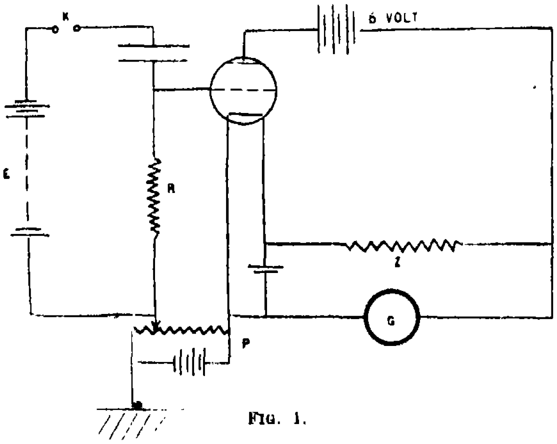

FIG. 1.

The circuit is shown in Fig. 1. A high resistance leak *R* of the order 10^{12} ohms is placed in the grid-filament circuit, and the ionisation current *c* flows through this leak to earth, thereby producing a steady potential *cR* volts across the grid, and a variation of *mcR* microamp. in the steady anode current of the valve. The normal anode current, when the key *K* is open, is balanced by the shunt circuit *GZ*. The mutual conductance *m* of the valve (G.E.C. type) is about 50 microamp. per volt, when the grid bias is -4 volts. Using a galvanometer of 10 divisions per microampere, a single division of the scale corresponds, therefore, to an ionisation current variation of 2×10^{-15} amp. This sensitivity can obviously be increased by using a still higher resistance leak.

Several tests have been made on the ordinary laboratory ionisation experiments and perfectly steady conditions have been obtained over long periods of working. The apparatus has been constructed in a small tin-lined box, fitted with an ebonite panel in which the anode and filament resistances were mounted. To ensure good insulation, the grid lead is brought out through a sulphur plug, and a vessel containing phosphorus pentoxide is placed within the box to keep the glass surface of the valve and leak as dry as possible.

No disturbance from external electromagnetic effects have been encountered, although tests were made when X-ray installations were in operation within the building, and the zero keeps perfectly steady over long periods. Since the anode voltage required is low (6 volts), large capacity cells can be used to minimise fluctuations in normal anode current. The high resistance leaks are best made from xylol-alcohol mixtures contained in narrow sealed tubes, and embedded in paraffin wax to improve external insulation. A potentiometer can be inserted as shown, if a null method of measurement is required.

In a recent test on the rate of decay of thorium, a galvanometer of sensitivity 100 divisions per microampere was employed, the sensitivity of the instrument being thereby increased ten-fold. A tendency for 'zero-creep' was observed. This is rapid when the potentials are first applied to the valve, but gradually decreases and becomes very slow (about 1 mm. per minute) after some time. This creep would appear to be due to leakage or accumulation of wall charges on the surface of the valve.

The application of the method to the X-ray spectrometer is now under investigation. Careful screening of the ionisation chamber and leads are necessary in this case, to avoid electromagnetic disturbances.

I am very much indebted to Prof. W. L. Bragg, who has given me every facility for this work.

Chemical and Biological Effects of Ultra-Sonic Radiation

ULTRA-SONIC radiation (frequency 723,000/sec.) was produced by means of a quartz plate (35 mm. × 35 mm. × 4 mm.).

The effect of this radiation on Ehrlich's carcinoma has been studied by B. Gözsi and found to have no specific effect on this tumour. The chemical action of this radiation has been studied by A. Szalay. The ultra-sonic radiation decomposes cane sugar into mono-saccharides but was found to have no effect on salicyl-phenylester, diphenylether, succinimid, methylal and the benzophenondiphenylacetal of Bruckner. It is not impossible that waves of a higher energy content might attack also such compounds and ultra-sonic radiation might furnish in the end a method for the measurement of the strength of chemical links.

Highly polymerised compounds such as starch, gum arabic and gelatine are easily depolymerised by the radiation employed, as judged by the rapidly falling viscosity. In the case of starch this result was supported by the iodine reaction which changed from blue to the red characteristic for dextrins. Taking into account the very limited effect of the radiation employed on simpler compounds, it seems probable that the observed depolymerisation was not due to the breaking up of chemical links in the stricter sense. It is hoped that ultra-sonic radiation might contribute to the knowledge of the highly polymerised state and to the meaning of molecular weight of highly polymerised substances.

For lack of funds our investigation has been broken off.

Research Items

Hindu Metal Images. Dr. F. H. Gravely and Mr. T. N. Ramachandran of the Madras Government Museum have compiled an illustrated catalogue of the South Indian Hindu metal images in the Museum collections (Bull., N.S., General Section, vol. 1, pt. 2). The Museum has acquired a particularly fine collection of these images, especially during the last thirty years, mostly from treasure trove. All are religious in purpose and are intended to remind worshippers of the divine. Each must conform to a pattern, laid down by tradition and prescribed in the craftman's handbook, which is regarded as a canon of divine origin. Hindu sculptors form a special caste. In these metal figures the emblems of the deities, especially the bow, arrow, mace, spear, and flowers that are prescribed to be held in the hands are often inserted separately, the images being cast with the hands in the holding position. Most images have more than one pair of arms. Of the three principal deities, Brahma has four faces and two pairs of hands, of which the upper right holds a rosary and the left a vessel with a spout. Vishnu carries a discus in the right, and a conch in the left of, usually, the upper pair of hands. Siva the destroyer is generally worshipped as a phallus in the central shrine of his temples; but images of him are also worshipped and are taken round in procession at festivals. His usual emblems in southern India are the axe and the antelope, but in the north the trident is more often seen. Other emblems of this deity are the drum, the skull-cap and various weapons of war. He has two aspects, the benign and the terrible. Siva is sometimes shown combined with Vishnu and sometimes with his consort Parvati, as right half male and left half female. By some it is believed that Vishnu cannot function without his sakti, the female principle.

Mexican and Ecuadorian Copper and Bronze Axes. A trial of the relative hardness of different parts of axes of copper and bronze from pre-Columbian Mexico and Ecuador has been made by M. A. Clement (*J. Soc. Américanistes*, Paris, N.S., 24, 1). The specimens examined are in the Musée d'Ethnographie du Trocadéro. Sixteen of the axes were of Ecuadorian origin, four were Mexican. The parts tested were the butt, the middle and the cutting-edge, the object of the investigation being to ascertain whether the last-named by its harder quality pointed to its having received special treatment. Brinell's test for hardness was used with a Bollée machine giving a pressure of 750 kgm. The Ecuadorian axes were all of pure copper with the exception of two which showed very slight traces of tin, and of sulphur respectively. They weighed from 190 gm. to 1,220 gm. The resulting table of coefficients of resistance shows a range of variation: for the butt, 67–112; for the middle, 59–103; for the cutting-edge, 72–121. In seven implements the cutting-edge is harder than the butt; and four are harder in the butt than at the edge. Two are equal in these two parts, but the middle differs; while one is uniform. The Mexican axes weigh from 450 gm. to 1,030 gm., three of them containing 1·8–3·8 per cent of tin. The coefficient of resistance is, for the butt a range of 48–56, for the middle 49–53, for the edge 50–56, the edge being harder than the rest of the implement. It is evident, therefore, that in both the Ecuadorian and the Mexican axes some process had been employed to render harder the part of the implement to be subjected to shock, and the investigation has produced no evidence against the hypothesis which has been put forward that these pre-Columbian coppers and bronzes were hardened by cold hammering.

Sponges from the North-Western Pacific. Dr. Yaichiro Okada, in his report on the hexactinellid sponges collected by the United States fisheries steamer *Albatross* in the north-western Pacific during the summer of 1906 (*Proc. United States Nat. Mus.*, 81, No. 2935, art. 12, 1932), gives a detailed account of this large and valuable collection of sponges, all from deep water, ranging from 59 to 1,800 fathoms. Altogether there are 42 species and sub-species belonging to 17 genera and 3 sub-genera, 29 species and sub-species being new. This very rich hexactinellid fauna shows a wonderful variety and the live animals must be unusually fine. Unfortunately, they are some of the most difficult of all animals to preserve in anything like their condition in life, although the shape and spicules can be well seen and these serve as diagnostic characters. Naturally, the spicules are very important, and these are well illustrated in clear text figures whilst photographs of the sponges new to science occupy the six plates. Those taken at the greatest depths are *Eurete irregularis* from 1,800 fathoms in brown mud, *Aphrocallistes aleutiana* from 1,046 fathoms dredged with grey mud, sand and pebbles, and *Pheronema surugensis* and *Hyalonema* (*Coscinonema*) *ovatum* from 918 fathoms with green mud and fine sand with *Globigerina*. In many cases the external appearance of different specimens of the same sponge are so dissimilar that only very careful examination of the spicules show them to belong to the same species. Thus *Hyalonema* (*Cycliconema*) *apertum solidum* new sub-species, has one form tulip-shaped, the other with a transversely expanded body like the fruit of a lotus; *Hyalonema* (*Cycliconema*) *hozawai* new species, being tulip-shaped in one form and spindle-shaped in another. In the single specimen of *Farrea sollasii*, there were numerous spindle-shaped larvæ in the maternal sponge body which are probably in an early stage of development.

The Genera *Dictyoconoides*, *Lockhartia*, and *Rotalia*. The mislaying of Carter's type specimens led to considerable confusion in the systematic classification of *Conulites* (*Dictyoconoides*, Nuttall). With the rediscovery of these specimens, Col. L. M. Davies (*Trans. Roy. Soc. Edin.*, pt. 2, vol. 57, pp. 397–428) has cleared up all previous difficulties. The seven species referred to *Conulites* (*Dictyoconoides*) are divided into true *Dictyoconoides* with numerous intercalary whorls in their spires and a new genus *Lockhartia* without such whorls. The distinctions between *Dictyoconoides* and *Rotalia* are discussed and emphasised. The systematic part of the paper is followed by an account of the development of the rotalids and dictyoconus group.

Distribution of Irish Plants and Animals. Dr. Lloyd Praeger has reviewed the problem of the distribution of the Irish flora and fauna in "Recent Views Bearing on the Problem of the Irish Flora and Fauna" (*Proc. Roy. Irish Acad.*, vol. 41, sect. B, No. 8, 1932, pp. 125–145). The author deals with various hypotheses since the time of Edward Forbes, who first discussed the problem of plant and animal distribution in the British Isles, and states that having studied this problem in Ireland for forty years, he still finds himself much where he was at the beginning, a supporter of Forbes's main thesis. Certain plants and animals, including the American and probably the Lusitanian element, survived the main glaciation, these oldest elements having migrated northwards in pre-glacial times or eastwards from America when the intervening barriers of sea were at least much less formidable than they are at present.

Identification of Timbers of *Eucalyptus* Species. Valuable investigation work is being undertaken in many parts of the world with the object of establishing simple methods of identifying timbers. Bulletin No. 67, published under the auspices of the Council for Scientific and Industrial Research, Commonwealth of Australia, comprises Technical Paper No. 5 of the Division of Forest Products and is entitled "Methods for the Identification of the Coloured Woods of the Genus *Eucalyptus*" by H. E. Dadswell and Maisie Burnell. In a foreword, Dr. Boas, chief of the Forest Products Division, states that the macroscopic and microscopic features of some Australian timbers have been studied and keys published for small groups of associated woods. No one had attempted the preparation of a comprehensive key covering any one genus. This work has now been commenced and the bulletin treats of one section of the important genus *Eucalyptus*. The development of methods for the correct identification of the timbers belonging to this genus is discussed. A preliminary separation was made on the basis of the colour of the wood, and two classes, (1) the coloured and (2) the pale coloured woods were arbitrarily formed. The present investigation was confined to the coloured woods, of which some thirty-seven species have been studied. Macroscopic and microscopic examinations were made according to the simpler forms of the usual procedure, the object kept in sight being the preparation of a simple identification key for use for commercial timbers of present and potential value. Such a tentative key is given at the end of the bulletin. The value of simple chemical tests for the separation of species difficult to distinguish by other means is also indicated. Photomicrographs of most of the species are included.

Yangtse-Kiang Flood of 1931. *Matériaux pour les Études des Calamités* (No. 28, pp. 338–351; 1932) contains an account of these great floods by L. Brandt, a member of the Flood Relief Commission in China. Though floods occur every year along the course of the river, especially in the neighbourhood of Hankow, those of 1931 were remarkable owing to their extent and duration. These were due to the unusually heavy rainfall at the end of July, when as much as 5–6 in. fell in one day. At Hankow, the river rose on August 19 to 53·6 ft. above its normal level, and by September 10 had only fallen 2·4 ft. It was estimated that the total area flooded was more than 46,000 square miles, that 45 per cent of the farms in this zone were destroyed, that the length of dams requiring repair was 2,800 miles, and that 10 million inhabitants were driven from their homes. The writer compares these figures with those for the Mississippi flood of 1927, which covered less than 20,000 square miles and deprived 600,000 persons of their homes.

Temperature of the Stratosphere. Dr. Bruno Rolf has described (*Medd. Stat. Meteorologisk-Hydrografiska Anstalt*, 5, No. 5, Stockholm, 1932), in French, the results obtained from *ballons-sondes* launched from Abisko during the years 1921–29. In this period 156 balloons were launched, and despite the sparseness of population in this far northern region (the latitude of Abisko is 68°), 66 of the balloons were recovered and returned; a reward of 10 Swedish crowns was payable for each balloon restored. Most of them fell in the south-east quadrant from Abisko, the Arctic Ocean being to the north-west. Inquiries as to how the sixty-six discoverers found the balloons elicited forty replies; nine saw the balloon actually descend. Twenty-four were returned within 15 days of launching, 36 within ten weeks, 48 within six months, and 60 within a year; one was not returned until 4 years 7 months after its ascent. The horizontal distances travelled by the balloons ranged from 2 km. to 576 km., the mean being 86 km. In sixty-five cases the traces of the Dines meteorographs carried by the balloons were perfectly readable. Very complete tables of the measurements are given in the memoir, providing data up to 20 km. in several cases. The most interesting and important outcome of the measures is to indicate an unexpected and considerable annual variation of the temperature of the stratosphere at this high latitude; the temperature is greatest in summer and least in winter, the range increasing with height above the tropopause, up to nearly 30° C. at 18 km. This is a phenomenon that may be of capital importance in connexion with the general circulation of the atmosphere.

High Pressure Research. The December 1932 issue of the *Proceedings of the American Academy of Arts and Sciences* contains two papers by Prof. Bridgman of Harvard University on the compressibilities and electrical resistances of materials under great hydrostatic or pneumatic pressure. The compressibilities up to about 1,200 atmospheres at 30° and 75° C. of eighteen sulphides, oxides, nitrates and halides belonging to the cubic system were measured by compressing the materials into cylinders about half an inch long and about the same diameter, which were then subjected to hydrostatic pressure and their change of length measured. The values over the first thousand atmospheres range from 1 to 9 parts in a million per atmosphere and decrease as the pressure increases. For halides they increase from the fluoride to the chloride, bromide and iodide in order, the increase from chloride to bromide being least. The electrical resistances of wires of fifteen metals most of which belong to the cubic system were measured at temperatures 0°, −78° and −183° C. and under pressures up to 7,000 atmospheres of helium. The decrease of resistance in each case is very nearly linear with pressure and at the maximum pressure amounts to about one per cent for columbium, rhodium, molybdenum, tantalum and tungsten, nearly 1·5 per cent for copper, nickel, iron, palladium and platinum, 2 per cent for gold, 3 per cent for aluminium and 9 per cent for lead, at 0° C., and the values are generally somewhat higher at the lower temperatures.

Oscillating Quartz Crystal as an Accurate Clock. Scheibe and Adelsberger, working at the Reichsanstalt, have developed the oscillating crystal as an accurate clock (*Phys. Z.*, Nov. 1932). The clock differs in some respects from those which have been studied in the United States. The quartz crystal is a thin rod supported at its nodal points in an evacuated tube and kept in a thermostat. It is driven by an oscillating valve at about 60,000 c.p.s. and this frequency is stepped down to 333 c.p.s. and used to drive a synchronous motor. The equipment was operated from mains through rectifiers and buffer batteries. One of the clocks was compared, over six months, with international time signals and the mean variation from the mean daily rate was 0·002 sec. The going of such a clock is too accurate to be checked astronomically over a short period. A second clock was constructed and the instantaneous rates of the clocks were compared from time to time. After an initial period of 'running in' the mean variation of the rates was 0·0003 sec./day. These figures compare very favourably with those of other high-precision clocks.

Calorific Values of Indian Woods. An investigation into the "Calorific Values of some Indian Woods" from the practical utilisation point of view, has been undertaken by Messrs. S. Krishna and S. Ramaswami at the Forest Research Institute. The results are published in *Forest Bulletin* No. 79 (Govt. of India Press, Calcutta, 1932). For practical purposes, the authors say, qualities other than the heat value have got to be considered. *Pinus longifolia*, for example, has been found to possess an average heat value of 5,015 cal. and *Quercus incana* of 4,600 cal.; but in spite of the difference the oak is preferred to the pine for fuel purposes. The choice of wood for fuel, therefore, does not depend upon its heat value alone; there are other factors of importance such as freedom from smoke, ease and completeness of combustion, rapidity of burning, sparking, etc., which must also be considered in making a selection. Calorific values of 150 species of Indian woods have been determined and the values are expressed on zero moisture and ash-free basis. Values of heartwood and sapwood have been determined separately. In general, although there are exceptions, the heartwood has been found to possess higher calorific value and this is particularly true in species containing resinous and volatile matter. The average heat value of Indian woods (broad leaved) has been found to be 5,016 cal., the value for conifers being about 5,120 cal.

Astronomical Topics

Astronomical Notes for March. Mars and Jupiter reach their most favourable positions for the year, being in opposition on March 1 and March 9 respectively. Neptune is near them, having passed opposition on February 27. No other planets are well placed for observation.

The sun crosses the equator and spring begins at 2 A.M. on March 21.

Two lunar occultations are visible in London; stars of the sixth magnitude disappear at 7.56 p.m. on March 4 and at 11.57 p.m. on March 7.

Mira Ceti is due at maximum early in March, but is too low to see except in the evening twilight. The most conveniently observable minima of Algol occur at 10 p.m. on March 12 and at 7 p.m. on March 15. Those using the B.A.A. Handbook are warned that one day should be subtracted from the dates given there from February 18 until the end of April.

Colour Temperatures of Stars. The observation of colour temperatures of stars has been in progress at Greenwich Observatory for some years, and the results so far obtained have now been issued in a special publication. The 'temperatures' finally deduced from the observations are in reality merely a convenient method of expressing the colours of the stars; and, though intimately related, are not actual temperatures of surface regions. The absolute determination of such colour temperatures by direct comparison with a terrestrial source is extremely tedious. Twenty-five suitable stars were accordingly selected in the first place, carefully compared with one another and with a terrestrial source (acetylene lamp) of known colour temperature, and finally used as standards for comparison with other stars. The actual observations of fresh stars were thus reduced to comparatively simple differential measures with one or more standard stars. The necessary photometric scale was obtained originally by the prism-crossed-by-grating method, but owing to the loss of time due to increased exposure involved, this was replaced by photographing a scale on the plate in the laboratory after exposure in the telescope. Results are given for 63 stars (including the 25 standard stars), and these are preceded by an introduction describing the theory involved as well as details of the apparatus used and practical methods.

New Comet, 1933 *a*. Mr. L. Peltier has made his fourth cometary discovery; he found a comet of the eighth magnitude on February 16. The two following observations were made by Dr. W. H. Steavenson at Norwood:

Feb. $17^{d}\,19^{h}\,41^{m}\,54^{s}$ U.T.	R.A. (1933·0) $23^{h}\,31^{m}\,20{\cdot}54^{s}$	N. Decl. $61^{\circ}\,56'\,52{\cdot}7''$
18 20 0 28	23 56 55·98	61 51 37·2

These will enable a rough estimate of the position to be made; there is not yet material for an orbit, but it is estimated that the perihelion is past, and that the distances from sun and earth are increasing, so the rate of motion may slow down.

A telegram from the U.A.I. Bureau, Copenhagen, gives the following elements and ephemeris of comet 1933 *a* (Peltier) computed by Drs. Anderson and Wyse:—

T	1933 February 7.63		
ω	137°	51′	1933.0
Ω	313	0	
i	84	55	
q	0·9980		

Ephemeris for 0^h U.T.

		R.A.			N. Decl.	
February	21	0^h	52^m	40^s	60°	36′
,,	25	2	21	40	54	44
March	1	3	23	16	46	6
,,	5	4	3	36	37	4

The brightness is diminishing.

Ephemerides of some other comets are given in the B.A.A. Handbook.

Halley's Comet in 1909–11

AN exhaustive discussion of the phenomena of Halley's comet and its envelopes, based on the examination of a large number of photographs taken at the Lick Observatory, at its Chile station, and at Mount Wilson, Johannesburg, Helwan, Kodaikanal, Cordoba, Yerkes, Tokyo, and Beirut, is given by Nicholas T. Bobrovnikoff in a memoir on "Halley's Comet in its Apparition of 1909–1911"; which appears in Lick Observatory Publications, Part 2. The outward motion of luminous patches in the tail was studied, and the repulsive force deduced, the assumption being made that the hyperbolic orbits of these objects were in the same plane as the orbit of the comet's nucleus. The resultant repulsive force was calculated in 31 cases; in 3 cases it exceeded 1,000 times gravity; in 4 cases it was between 100 and 1,000 times; in 6 cases it was between 50 and 100 times. The two tails of the comet on May 29, 1910, are traced on page 457 of the memoir. That of Bredichin's type I is nearly straight, the indicated repulsive force ranging from 9 to 16; the tail of type II is highly curved, the repulsive force being only 0·1 to 0·2. The presence of this curved tail explained the surprising fact that a tail could be seen in the morning sky for some time after the nucleus and straight tail had become evening objects. On account of the curvature of the tail, the author is doubtful whether the earth passed through any portion of it; in any event only the outlying portions could have been traversed.

A study is made of the curved envelopes that surrounded the comet's head. A parabolic outline has generally been assumed for these, but the author finds, as Bond had done in his study of Donati's comet of 1858, that the catenary gives a better representation; it is suggested that the shape may be accounted for if the different envelopes exert some electrical action on each other.

A description was given by Barnard of the appearance of the nucleus. What was taken with a low power to be the nucleus was seen with greater power to be a dense nebulosity of a bluish colour, with a stellar nucleus, 2″ or 3″ in diameter. It may be noted that a similar small nucleus was seen with large instruments at the near approach of the comet Pons-Winnecke to the earth in June 1927.

Reasons are given for believing that the activity of emission, responsible for sending out the envelopes and luminous masses in the tail, is not confined to the small nucleus, but extends to some distance from it. Comparison is made between the envelopes in Halley's comet with those of Morehouse's comet of 1908, which were studied by Eddington. In the case of Morehouse the envelopes showed rapid motion, sensible in a few minutes, and the repulsive forces were several thousand times that of gravitation.

There were a few cases of sudden explosive action in the case of Halley's comet, notably on May 13 (Innes) and May 24 (Barnard), but on the whole the disturbances seem to have been much weaker than in Morehouse's comet.

In 1835 Bessel found evidence of rotation of the nucleus; this phenomenon was therefore looked for, but the fact that jets around the nucleus retained their direction for some days, in one case for a week, makes rotation unlikely. Examination was made whether any of the secondary regions of activity round the nucleus gave evidence of separating from the comet (a phenomenon noted in Biela's comet, in the great 1882 comet, and in Taylor's of 1915). The author thinks that Halley's comet may have been on the verge of disruption, but that this was never quite reached.

An estimate is made of the mass of Halley's comet. The author gives 3×10^{10} of the earth as a lower limit. This is about the mean of the widely different values given by Orlow, but in neither case is it considered more than a guess. As regards the total brightness of the comet in 1910, Holetschek's results are quoted that the comet has not appreciably declined either in light or in length of tail during the last five apparitions. A very different estimate was reached by many English observers in 1910, but this was due to twilight and the comet's low altitude; in the tropics the tail was described as like a great searchlight beam, 140° long; the great length was due to its nearness to the earth. The length in linear units was difficult to compute, owing to great foreshortening; according to Holetschek's discussion it was about a quarter of an astronomical unit on April 21, two days after perihelion, and increased to nearly a unit at the end of May.

The memoir also discusses the comet's spectrum; the continuous spectrum of the nucleus closely resembled that of the stars of solar type λ Serpentis and α_1 Centauri. There is, however, a more rapid falling off of light at the violet end in the comet's spectrum. In this respect the comet resembles the brighter asteroids; the author considers that it denotes the presence of iron in each case.

The author deserves thanks for this painstaking memoir, which describes in close detail the phenomena exhibited by the comet during the time of greatest brightness. Many beautiful photographs are reproduced, including some spectra, and there are many diagrams. The author commenced the work while he held the Martin Kellogg fellowship at Lick Observatory (1927–1929) and finished it when he was a research fellow in the University of California.

A. C. D. CROMMELIN.

Carbon Dioxide in the Sea

IN the biochemical study of life processes in the sea, an understanding of the rôle of the carbon dioxide system is very desirable. In virtue of the excess base always present, sea water contains not only free dissolved carbon dioxide but also many times as much in combination as carbonates and bicarbonates. The equilibrium existing in this system under naturally occurring conditions is a complicated one. It may be displaced by photosynthesis, changes in calcium due to vital processes, decay of dead matter, temperature, salinity and pressure. To the geologist also its study is of importance since it controls the formation of calcareous sedimentary rocks.

The commonest line of attack is to determine hydrogen ion concentration and excess base. The direct determination of carbon dioxide has been a tedious business at best and practically impossible on board ship. For this purpose a portable manometric modification of the Van Slyke apparatus has been introduced by Greenberg, Moberg and Allen,[1] who claim for it the virtues of speed, accuracy and serviceability at sea.

In 1930 a committee, set up by the International Council for the Exploration of the Sea, met at Helsingfors, to go into the whole question of carbon dioxide in the sea. The account of its labours is now to hand.[2] The experimental work covering most aspects of the equilibrium of interest to the marine investigator, appears to have been carried out with exemplary care. It is backed by a mathematical treatment, based on the activity concept, relating the first and second dissociation constants of carbonic acid to the determinable quantities.

There is now no need to undertake the direct determination of carbon dioxide in sea water. From excess base and hydrogen ion determinations, the concentrations of total and free carbon dioxide and of carbonate and bicarbonate ions may be read off directly from tables. A knowledge of temperature and salinity is also required but determination of these is a routine matter in almost all oceanographical work. Furthermore, over large areas of the ocean, excess base has been found to be proportional to the salinity. When this is the case, a rapid colorimetric determination of hydrogen ion concentration gives the key to the whole carbon dioxide system. The importance of this is great since the solution of marine biochemical problems necessitates the accumulation of a large amount of data often under difficult working conditions.

Owing to the thoroughness of the investigation, the conclusions and tables are intermingled with a large mass of mathematical reasoning, without perusal of which they cannot be properly understood. In consequence, the present writer fears that the non-mathematical, non-German-speaking biologist may be tempted to pass over one of the most outstanding contributions to oceanography in recent years. It seems a pity that the tables have not been published with an English summary sufficient for the field worker who is prepared to take their derivation on trust.

Accurate use of the tables requires a knowledge of the temperature coefficient of hydrogen ion concentration in sea water and in the buffers used for colorimetric comparison and also of the dissociation constants of the indicators used for sea water work. This subject was studied by Buch some years ago.

Re-solution of calcium in the sea and the formation of limy deposits at great depths is affected by the displacement of hydrogen ion concentration with pressure and the increased solubility of carbon dioxide. This topic, discussed in the report, has been further extended by Buch and Gripenberg in another publication of the International Council.[3] The change in hydrogen ion concentration with depth is considerable, particularly with an acid water. The *p*H of a water brought from 10,000 metres to the surface would increase by 0·2–0·3 unit. With increasing depth there is a notable rise in bicarbonate ion, accompanied by a decrease in free carbon dioxide and sometimes of carbonate ion. L. H. N. C.

Chilean Insect Parasites for New Zealand

RECENTLY Dr. D. Miller of the Cawthron Institute, Nelson, visited South America for the purpose of studying, among other problems, the influence of the Chilean saw-fly, *Antholcus varinervis*, upon the various species of plants belonging to the genus *Acæna*, the foliage and inflorescences of which are attacked by the larvæ of this insect. Certain species of *Acæna* in New Zealand are important weeds which occupy extensive areas of valuable pasture land, while their burrs reduce the market value of sheep's wool to the extent of some £250,000 annually.

During the researches in Chile, it was noticed that the *Antholcus* larvæ did much more damage to the foliage of the thin-leaved Chilean *Acæna* than to the thick-leaved forms, a feature of considerable value, since the important New Zealand species of the genus are of the former type. One of the difficulties in the utilisation of phytophagous insects for the control of weeds is that there is a danger of the insects extending their food range to plants of economic value; to safeguard this as much as possible involves very careful study. In the case of *Antholcus varinervis*, however, the insect itself overcomes this difficulty in that its larvæ are active throughout the winter months when there are, with the exception of strawberry, no useful rosaceans with available foliage; and in the case of strawberry it has been found that the larvæ will not touch the foliage in the presence of *Acæna*. Dr. Miller successfully transported to New Zealand a large consignment of *Antholcus* pre-pupæ packed in soil and carried in cool store (40° F.). In New Zealand the insects have developed and attacked *Acæna* in a very satisfactory manner, and there is every prospect of an outstanding success in the control of the weed.

When dealing with *Antholcus* it was found that certain species of Chilean *Thynnidæ* attacked cockchafer larvæ. Just as in many parts of the northern hemisphere, the control of native cockchafers is one of the most outstanding agricultural problems in New Zealand, where the larvæ destroy great areas of pasture as well as various crops the roots of which are attacked, while the beetles, as defoliators, cause extensive destruction to turnip and rape crops. Therefore the importance to New Zealand of the Chilean thynnids was at once recognised and arrangements were made for one of the species to be dispatched to the Dominion; this species, *Elaphroptera dimidiata*, is now being studied at the Cawthron Institute. It is of importance to note that the two parasites, *Antholcus varinervis* and *Elaphroptera dimidiata*, both belong to groups not represented in the New Zealand fauna, and, when established in their new environment, should not be seriously influenced by indigenous entomophagous insects. Further, the New Zealand cockchafer larvæ are remarkably free of parasites, a fact that will benefit the influence of *E. dimidiata* upon these hosts.

In the periodical transport of parasites from Chile, one of the difficulties to be overcome was the absence of direct shipping, which necessitated the transport of material through the tropics by way of Panama. However, the British Consular Service rendered invaluable assistance and willingly undertook the shipping of consignments from Chile and their transhipment to New Zealand boats at the Panama Canal; this system has worked admirably. The researches in Chile were carried out in collaboration with Bro. Claude Joseph (who had been undertaking researches on behalf of New Zealand for some time), at Temuco and in the surrounding Araucanian territory. Bro. Joseph has taken a supply of *Elaphroptera dimidiata* to France in the hope that it may prove effective in the control of the European cockchafer (*Melolontha melolontha*).

Correlation of Meteorological Data

IN a recent publication, Sir Gilbert Walker discusses certain meteorological and solar statistical relationships worked out by E. W. Bliss (*Mem. Roy. Met. Soc.*, 4, No. 36). Many years have elapsed since the work of Tesseirenc de Bort and Hildebrandsson showed that there are regions where the changes of certain meteorological elements are correlated with the changes in the same or different meteorological elements in places so far distant that the discovery of the connexion came as a surprise, and seemed to open up prospects of a greatly increased understanding of the workings of the general circulation of the earth's atmosphere. The work has had practical results in seasonal weather forecasting, for example, in the predictions of the character of the Indian monsoon organised by Sir Gilbert Walker, but has thrown very little light on the physics of the general circulation. So far from providing important generalisations such as would simplify the study of world meteorology, it has resulted in an enormous number of statistical relationships from which cause and effect can seldom be disentangled.

Sir Gilbert's present paper is an attempt at arriving at more definite ideas about the relationships of three important groups of action centres which have been called the North Atlantic, the North Pacific and the Southern oscillations. Each oscillation is defined as the algebraic sum of the deviations of meteorological elements at a number of places in or near the area from which it derives its name. For the North Atlantic, the pressure difference between the Azores and Iceland, and consequently the intensity of the 'westerlies' of that ocean, is an important ingredient in the oscillation. Tables of correlation coefficients are given between the values of the oscillations in individual seasons and pressure, temperature and rainfall at places widely distributed throughout the world, and between the oscillations themselves. As sunspots are believed to be related to the energy radiated by the sun, and it is this energy that maintains the general circulation of the earth's atmosphere, coefficients are also given between the figures for sunspot activity and those for the three oscillations.

The tantalising nature of the results obtained in such studies is well illustrated by the existence of a correlation coefficient of + 0·84 between the winter and subsequent summer values of the Southern oscillation. This degree of connexion is remarkable for meteorological conditions separated by an interval of half a year, but the result has not so far been explained on any physical basis.

University and Educational Intelligence

CAMBRIDGE.—The Rockefeller Foundation has given £500 to the Molteno Institute of Parasitology for the purchase of instruments and for assistance in connexion with investigations to be carried out by Prof. D. Keilin.

The Goldsmiths' Company has presented £12,500 to increase the endowment of the Goldsmiths' professorship of metallurgy. The original offer of £10,000 has been increased to the larger sum in view of the fall in rates of interest.

The Gordon Wigan prize for chemistry has been awarded to Mr. T. P. Hoar, Sidney Sussex College, for a thesis entitled "On the Mechanism of the Corrosion of Iron and Steel".

THE twelfth annual vacation course in spectroscopy, interferometry, nephelometry and refractometry will be held on March 30–April 5, at the Zoological Institute of the University of Jena. Further particulars and a syllabus of the course can be obtained from Messrs. Carl Zeiss, Ltd., Mortimer House, 37–41, Mortimer Street, London, W.1.

THE Board of Education is prepared to consider applications for full-time studentships from teachers with at least five years' teaching experience, who desire financial assistance to follow courses of advanced study at universities or other institutions at home or abroad. Particulars of the awards and application forms are obtainable from the Board of Education, Whitehall, S.W.1.

THE sixth annual list of holiday courses in Europe has been prepared and recently published by the League of Nations' Institute of Intellectual Co-operation, acting under the recommendation of the Directors of National University Offices. The list is very comprehensive but only includes those courses which are open to foreigners. Such details as are available are given with each course, together with descriptions of certificates, etc., awarded, facilities for travelling and residence, and names of officials to whom to apply for further information. The pamphlet is published in English, French and German. The English edition can be obtained from Messrs. George Allen and Unwin, Ltd., 40 Museum Street, London, W.C.1 (price 2*s*.).

Calendar of Nature Topics

Spring Wheat

Great Britain expects at least twice the yield per acre of wheat that the great producing areas of the world obtain, and distinctly more than the average yield of France and Germany, because the climate is admirably suited to the production of heavy yields. Only Belgium and Denmark obtain greater returns per acre. High yields in Great Britain are associated with the distributed rainfall and long period of growth obtained by autumn sowing. Spring sowing, on the other hand, is the practice in countries having severe winters and hot summers, while elsewhere the use of quickly maturing varieties is necessary when only a few months of the year are really favourable to the growth of wheat. A short growth period is associated with a low level of yield. In the ordinary way, spring-sown wheat is rare in England and is only grown because some circumstance has interfered with sowing at the normal time. This spring, however, it is to be expected that more wheat will be drilled than usual. The crop now stands in a relatively favourable position to the other cereals since the price is known in advance. Early maturity is the important quality in a spring wheat and special varieties, usually French, are used. The ordinary autumn wheats are not suitable, but one of them, Little Joss, is exceptional in this respect and has quite a good reputation as a spring wheat. In order to give a return approaching that of the ordinary wheat, the spring sown crop requires every help that a mellow and fertile seed-bed can provide, and if these conditions can be secured in February the better the prospect for the crop.

The Mole's Winter Store of Earthworms

In the middle of last century Edward Jesse, in his "Gleanings of Natural History", first published the story that, during the winter, moles (*Talpa europæa*) form underground chambers in which earthworms are stored, so mutilated that they cannot escape; but the belief seems to be widespread amongst mole-catchers. On the other hand British naturalists have generally thrown doubt upon the story, regarding it, like Barrett-Hamilton, as "a result of imagination rather than an invention", supported by "no trustworthy evidence". But good evidence did exist even when Barrett-Hamilton wrote. In 1886 Fr. Dahl recorded that he had found in a mole's fortress as many as 1,280 earthworms stored up in the nest-cavity and in the adjoining runs, where they were firmly embedded in the mud walls in small groups of about ten in number; and in 1891 Prof. Ritzema Bos recorded that in February he had received about 300 earthworms found in a mole's fortress. In both cases the worms were damaged: Dahl regarded the damage as being due to forced cramming into the wall; Bos described in careful detail that the mole had bitten off from three to five of the foremost segments of each worm; that the wounded fore end had been covered by a new skin, but no other regeneration had taken place, perhaps because the winter temperature had been too low for this vital process.

Experimental Evidence of Storing by Mole

If further testimony to a remarkable habit was necessary, it has been provided by the experiments of Magnus Degerbøl with a mole he kept in captivity for about six months during the winter of 1922–23. When the mole was supplied with more worms than it could eat, and the earth in its box was only a few centimetres deep, it scraped aside the earth in one corner, seized a worm, crammed it into the hole to the accompaniment of a crunching noise, and finally covered it up with earth which it patted into firmness with its snout. Ten worms were thus buried, and when Degerbøl retrieved them he discovered that one or more of the anterior segments had been bitten clean off. When deeper earth was placed in the box so that the mole could make runs below the surface, it carried the worms below, burying 49 large individuals in 40 minutes. When the runs were dug out the worms were found half coiled and embedded in the walls, a thin layer of earth separating each two worms; fourteen had their foremost segments bitten off, a single one had its hind segments nearly bitten off, and 34 were unhurt. This was the only occasion on which Degerbøl found the anterior end undamaged, and he attributed it to the embarrassment of the mole at the overwhelming supply of worms, a condition of affairs not likely to arise in natural conditions. The mole touched the surface of a worm with its snout before deciding which was the fore end.

The Purpose of the Mole's Store

As to the purpose of these stores, the existence of which can now be accepted, more information is required. The general idea is that they form a reserve of provender laid by to serve when food becomes scarce in hard weather. But Jesse stated that the basins "appear to be formed in the winter and to have the chief supply of worms deposited in them during the spring months", and Dahl found that the stores were greatest after a prolonged frost—periods at which a true winter store would be at a low ebb. May it be that the storing impulse is not seasonal, and that the size of the store after frost depends either upon the ease with which worms are caught in cold weather, as Dahl suggests, or upon the slowness of regeneration of the tip in cold weather, so that the worms cannot escape so quickly, as suggested by Degerbøl? Some mystery still surrounds the mole's stores, but simple field observations which could be carried out now and during the spring ought to solve the problems.

Spring Increase of Planktonic Diatoms

The latter part of February may show the beginning of the spring maximum of planktonic diatoms in the sea. All-important as food for the small floating animals—especially the larvæ of Crustacea, worms, molluscs and echinoderms which hatch out during and after this large outburst—the diatoms every year multiply in huge numbers during the spring, dwindling again later after depletion by the hordes of creatures feeding on them. In some years this diatom maximum may be early, in other years late, but it always occurs between February and April inclusive.

In 1932 the maximum occurred in the English Channel near Plymouth in March. On March 21, at a point several miles outside the Eddystone Lighthouse, the following diatoms in order of abundance were mainly responsible for the large numbers:—*Coscinodiscus granii*, *Bacillaria paradoxa*, *Skeletonema costatum*, *Chaetoceros sociale*, *Coscinodiscus concinnus*, *Thalassiosira gravida*, *Biddulphia regia*, *Biddulphia sinensis*, *Thalassiothrix nitzschioides*. Most of these species are common members of the spring plankton in those regions, but it is unusual to find *Bacillaria paradoxa* so far from the coast in such huge numbers; and the presence of the two *Biddulphia* species at this time of the year in profusion is abnormal, their usual season being late summer, autumn, and the early winter months.

March Winds

The traditional breeziness of March is expressed in numerous proverbs, and in the French Revolutionary Calendar of 1793 the period February 19–March 20 was the month *Ventôse*—'windy'. At Kew Observatory the average wind velocity in March is greater than in any other month, though only slightly exceeding that in February and April, but the impression of windiness is probably to a large extent subjective, resulting from a combination of causes. The relative humidity is decreasing rapidly, giving the air a brisk drying quality, and the mud of

February turns to dust, which is stirred by the breeze. The warming of the ground makes the lower air unstable, sometimes forming small dust-whirls. The broken clouds appear to drift rapidly, forming a 'windy sky'. Boisterous weather is not expected to last throughout the month, however, and it is proverbial that "if March comes in like a lion, it will go out like a lamb".

Societies and Academies

LONDON

Royal Society, Feb. 16. P. M. S. Blackett and G. Occhialini: Some results of the photography of the tracks of penetrating radiation. About 500 photographs have been taken of these tracks, using an automatic method by which the passage of the particles through two counters causes the expansion to occur. The most striking feature of the results is the extraordinary variety and complexity of the multiple tracks, some of which show more than twenty separate tracks. An analysis of the nature of the particles producing these tracks leads to the conclusion, already put forward tentatively by Anderson (*Science*, Sept. 9, 1932), that some of the tracks are due to particles with a positive charge, but with a mass comparable with that of an electron rather than with that of a proton. These 'positive electrons' seem to be produced during the nuclear collision processes giving rise to the showers. W. E. Garner and H. R. Hailes: Thermal decomposition and detonation of mercury fulminate. Single crystals of mercury fulminate have been heated in vacuum at temperatures between 100° and 150° C. and a detailed examination made of the decomposition which ensues. In vacuum the thermal decomposition passes into detonation at 105°–115° C. The conditions which govern the inception of detonation have been investigated. The thermal decomposition occurring below the ignition temperature occurs in three stages: (1) a quiescent period during which there is a slight browning of the crystal, the decomposition being mainly superficial; (2) a period of acceleration of the rate of reaction; and (3) a region where the equation of the first order applies. These results have been interpreted as due to the commencement of thermal decomposition in the Smekal cracks of the fulminate crystal and the spread of the reaction to crystallites isolated by the destruction of the cementing material. The critical increment of the thermal reaction is approximately 30 k. cal. C. R. Bailey and A. B. D. Cassie: Investigations in the infra-red region of the spectrum. (8) The grating spectrometer previously described has been applied to certain bands in the infra-red spectra of sulphur dioxide, carbon disulphide, and ozone. The upper limit of resolution at which the spectrometer has been used corresponds to a slit width containing some 2 cm.$^{-1}$. As a consequence, a previously unsuspected *Q* branch has been revealed in one of the sulphur dioxide bands, which makes it certain that this molecule is an isosceles triangle with a vertical angle of 120°. The structure of ozone is briefly discussed, but sufficient evidence is not available for a definite conclusion.

PARIS

Academy of Sciences, Jan. 9 (*C.R.*, 196, 73–143). L. Lecornu: The variable rotation of a solid of revolution. C. Matignon and M. Séon: The action of steam on hexane. Description of experiments on the reaction between hexane and variable proportions of steam at 1050° C. in the presence of zirconia as catalyst. The main products were hydrogen and carbon dioxide. Similar results were obtained when benzene was substituted for hexane. Lucien Daniel: The modifications of the reserve function in various plants when submitted to intermittent watering. P. Dubreil: Mixed total intersections in three dimensional space. S. Banach and S. Mazur: The linear dimension of functional spaces. J. Schauder: Linear partial differential equations of the elliptic type. Caius Jacob: A mixed problem in the circular ring. J. Colomb: The Amsler planimeter. Corrections and additions to work on the same subject by Resal. Pol Ravigneaux: A new apparatus for calculation with slide rules. G. P. Arcay: The influence of vibrations on the rate of chronometers. Constantin Woronetz: The influence of temperature on the stability of gyratory movements of fluids. J. Dufay: The brightness of the extragalactic nebulæ and the absorption of light in the Milky Way. S. Soboleff: A problem of the diffraction of waves. R. de Mallemann and P. Gabiano: The magnetic rotatory power of chlorine and of hydrochloric acid gas. The atomic rotation of chlorine gas is about ten per cent higher than that found in the vapours of chlorine compounds: the value for hydrogen chloride is five per cent higher than the sum of the atomic rotations of its constituents. Ny Tsi-Ze and Chien Ling-Chao: The influence of pressure on the photographic sensibility to various monochromatic radiations. The influence of pressure on the photographic sensibility varies greatly with the wave-length and decreases as the wave-length decreases. Mlle. Suzanne Veil: The rhythm of crystallisation caused by the diffusion of alkaline carbonates in gelatine. E. Carrière and Mlle. Carlini: The decomposition of thiosulphuric acid in dilute solution at the boiling point. The products of decomposition were sulphur dioxide, sulphur, sulphuric and pentathionic acids. Mlle. A. Pinguet: Oxyallantoin. Pariselle and Barbier: Contribution to the study of the cadmium tartrates. P. Carré and D. Libermann: α-Phenyl-γ-oxybutyric acid and its lactone. Wiemann: The synthesis of vinylpropenylglycol. Mme. Ramart-Lucas and Mlle. Wohl: The colour and structure of amides. The study of the absorption of substituted amides leads to the conclusion that an amide, in the liquid or dissolved state, is a mixture of two isomers in equilibrium, amide and iminoalcohol. Mme. Bruzau: The spontaneous resolution into active isomers of 4-methoxy-methyldesoxybenzoin, $C_6H_5.CH(CH_3).CO.C_6H_4.OCH_3$. F. Roman and M. Gautier: The presence of a Bathonian pyritic level in the region of Rar-el-Maden, near Nemours (Oran). Idrac: An apparatus capable of measuring and recording vertical submarine and sublacustral currents. J. Duché: Obtaining clones with fixed properties in the Actinomyces. J. Millot: The systematic position of the spiders of the genus *Liphistius* according to their internal anatomy. Raymond-Hamet: The variability of the effects of sparteine on the intestine in situ. Philippe Fabre and Pierre Faidherbe: The constancy of the limiting slope, inverse variations of the chronaxy and of the linear constant in the course of electrotonus of the nerves. Z. M. Bacq and V. Henri: A spectroscopic proof of the formation of substances by the stimulation of the cardiac nerves. G. Sandulesco, Wang Wen Tchung and A. Girard: Contribution to the knowledge of female sexual hormones. The picrates and styphnates of the crystallised hormones equilenine and folliculine were prepared, and found to be of service in purifying and separating these hormones.

SYDNEY

Linnean Society of New South Wales, Oct. 26. GLADYS CAREY and LILIAN FRASER: The embryology and seedling development of *Aegiceras majus*, Gaertn. This mangrove is characterised by vivipary. After fertilisation the embryo sac enlarges, first by resorption of the nucellus and later by penetration into the micropyle. The cells of the integument in the region of the micropyle, being meristematic, keep pace (by their division) with the advancing sac so that the sac does not at any time emerge from the micropyle. At the same time numerous endosperm nuclei are formed which later give rise to an endospermic tissue in the much enlarged sac. The cells of the integument divide rapidly, and so folds are formed around the embryo sac. The fruit is shed from the tree and under favourable conditions the embryo becomes established in the soil. C. DEANE: New species of Corylophidæ (Coleoptera). Descriptions of new Australian species of Corylophidæ (Coleoptera) under two genera, one of which is submitted as new. Two other genera, not previously figured, are illustrated. IDA A. BROWN: Late Middle Devonian diastrophism in south-eastern Australia. During this period, the meridional geosyncline of earlier Palæozoic times was finally closed up and the south-eastern portion of Australia was permanently welded on to the continental massif. This period of diastrophism appears to be equivalent to the Brunswickian or Arcadian revolution of eastern North America and to the disturbance represented by the unconformity between Lower or Middle and Upper Old Red Sandstone of northern Britain. It may be regarded as one of the major orogenic epochs of the Palæozoic era.

VIENNA

Academy of Sciences, Oct. 27. R. WEGSCHEIDER: (1). Further contributions to photochemical kinetics. Formulæ are derived for the course of photochemical reactions from the light-absorption of all the substances present. (2) Photochemical transformation of *o*-nitrobenzaldehyde (ii). The available data concerning this change in the light may be interpreted by assuming a partial inactivation of the molecules affected by light. ADOLF FRANKE, ALFRED KROUPA and SOLON HADZIDIMITRIU: A synthesis of α-alkyladipic acids. A general method of synthesis is applied to the preparation of α-n-hexyl- and α-n-octyl-adipic acids. The acids obtained are identical with those which were prepared earlier from oxydodecane and were inaccurately described as α-n-amyl- and α-n-heptyl-pimelic acids. LUDWIG OTTO KOBLMULLER and RUDOLF VIERTHALER: An arrangement for transferring single-cell cultures to solid nutrient media. Use is made of an adjustable arm carrying a nickel wire pointed to a thickness of 1 micron by treatment with a nitrite solution. FRANZ WERNER and RICHARD EBNER: Results of a zoological expedition to Morocco (1930): (5) Scorpions. The scorpion fauna of Morocco has been revised and a new species, *Buthus barbouri*, and a new sub-species, *Scorpio maurus legionis*, added. FRANZ WERNER: A new snake from the Cyclades Islands. This new species, *Elaphe rechingeri*, is allied to *E. longissima*, which occurs rarely and only in the extreme west of the Greek mainland. HERMANN TERTSCH: Results of cleavage measurements of galena.

Nov. 3. KARL PRZIBRAM: Recrystallisation and blue rock-salt. (1) The rarity of the blue salt is attributed to the fact that its formation requires in addition to the actions of radiation and pressure, also a low re-crystallising power, this being occasioned by the presence of impurities. (2) Observations on natural blue rock-salt. (3) Further representations of this salt show the formation of diffusion regions, the arrangement of the colour in growth zones and along slip surfaces, and the connexion between the blue coloration and the presence of sylvine. FRANZ KAHLER: Geology of the Karawanken Mountains. FRANZ HERITSCH: The northern boundaries of the Carinthian Alps. FRANZ KAHLER: The Rattendorf Alm and the Nassfeld region. FRANZ KAHLER and FRANZ HERITSCH: The stratigraphic arrangement of the Nassfeld strata. KARL METZ: (1) A fauna from the Hochwipfel strata of the Carinthian Alps. Together with forms capable of only general definition, the following were identified: *Schellwieniella crenistria* Phill.; *Retzia* (*Hustedia*) *radialis* Phill.; *Spirifer trigonalis* Mart.; several *Rhombopora* species, comparable with American forms; *Chainodictyum laxum* Foerste; *Chainodictyum laxum* var. *minor* Ulrich, and a new *Septospora* (?). (2) Details of the Nassfeld strata from Schulterkofel westwards. HEIMO HERITSCH: Geology of the crystalline zone of the Gail valley. WALTER PASSER: A static process for the calculation of networks of lines.

Nov. 10. G. GORBACH and A. SCHONBECK: Influence of hydrocyanic acid on bacterial proteases. In certain cases, hydrocyanic acid enhances the degradation of the proteins of culture media by *Bacillus pyocyaneus*. ERICH NIEDERDORFER: Measurements of the heat interchange over snow-covered soils. MARIETTA BLAU and HERTHA WAMBACHER: Experiments on the photographic detection of protons liberated by neutrons (2). These protons may be readily detected by using Imperial process plates previously desensitised by treatment with pinakryptol-yellow. The greatest lengths of path thus observed indicate, for the neutron energies, considerably higher values than have been formerly assumed. FRITZ SOCHTING: Vibration amplitudes in resonance. ARTHUR HAAS: Possibility of a cosmological interpretation of the quantum. FRANZ HERITSCH: The Carinthian Alps (1 and 2). ERICH HABERFELNER: Geological survey between Plöckenpass and Hochwipfel. HANS SEELMEIER: Graptolites from the Gugel (district of Stranigeralm).

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, 18, 633–676, Nov. 15, 1932). A EMERSON WARREN: Xanthophores in *Fundulus*, with special consideration of their 'expanded' and 'contracted' phases. Isolated scales in Ringer's solution released cells which included xanthophores in various states, all of which showed distinct cell outlines, while some had extended processes. Normal freshly fixed material from fish adapted to yellow and to black backgrounds showed cells with nuclei, containing sulphur yellow and orange carotinoids and also reddish granules; in contraction the latter were not always drawn towards the central body of pigment. It is concluded that xanthophores, like melanophores, are of relatively fixed and constant form. WILLIAM ROWAN: Experiments in bird migration. (3) The effects of artificial light, castration and certain extracts on the autumn movements of the American crow (*Corvus brachyrhynchos*). The normal southward autumnal migration was reversed, to some extent, after increasing artificially the length of the day for five weeks during October-November 1931. Castrated birds went southwards. A non-migratory group was produced by treating caponised birds with injections of an extract from male human urine. All birds migrating maintained the north-west-south-east line of flight characteristic of Alberta crows, although liberated at a non-migratory season. Maps showing distribution of recovered birds and records of observations are given. FRANK H. CLARK: Hydrocephalus, a hereditary character in the house mouse. This lethal character is transmitted as a simple recessive unit character, and it may be linked with the gene producing a flexed tail. M. DEMEREC: Rate of instability of miniature-3 gamma gene of *Drosophila virilis* in the males in the homozygous and in the heterozygous females. W. M. DAVIS: Glacial epochs of the Santa Monica Mountains, California. A new coastal road has provided exposures indicating that the region has suffered three periods of sea abrasion at different levels, with which alternated two epochs of withdrawal of the sea and platform emergence. These withdrawals are believed to mark the beginning of two glacial epochs, but there is no evidence of glaciation in the Santa Monica Mountains themselves, which are too low for such records. G. A. MILLER: The commutator subgroup of a group generated by two operators. L. A. MACCOLL: On the distributions of the zeros of certain analytic functions. MAURICE FRÉCHET: On the behaviour of the *n*th iterate of a Fredholm kernel as *n* becomes infinite. NEAL H. MCCOY: On the function in quantum mechanics which corresponds to a given function in classical mechanics.

Forthcoming Events

Monday, Feb. 27

ROYAL GEOGRAPHICAL SOCIETY, at 5.30.—Sir Douglas Mawson: The Banzare Film (illustrating the recent voyage of the *Discovery*).

Tuesday, Feb. 28

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—Major G. St. John Orde Browne: "Economic Development in Tropical Africa as affected by Labour Supply".

Wednesday, March 1

BEDFORD COLLEGE, LONDON, at 5.15.—"Contemporary Developments in Science". Sir Henry Dale: "Ultramicroscopic Organisms and the Troubles which they Cause".

UNIVERSITY COLLEGE, LONDON, at 5.30.—Prof. A. E. Richardson: "Library Design".

SOCIETY OF PUBLIC ANALYSTS, at 8.—(at the Chemical Society's Rooms, Burlington House, Piccadilly, W.1).—Annual General Meeting.

Thursday, March 2

ROYAL INSTITUTION, at 5.15.—A. R. Hinks: "Geography in the Public Service".

INSTITUTION OF CIVIL ENGINEERS, at 6.—(Extra Meeting).—V. J. P. de Blocq van Kuffeler: "The Zuider Zee Works".

Friday, March 3

BEDSON CLUB, at 6.30.—(in the Chemistry Theatre, Armstrong College, Newcastle-upon-Tyne).—Prof. R. Whytlaw-Gray: "The Accurate Determination of Atomic Weights by the Method of Limiting Densities".

PHYSICAL AND CHEMICAL SOCIETIES OF THE UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, at 7.—Prof. W. A. Bone: "Britain's Coal Problems".

GEOLOGISTS' ASSOCIATION, at 7.30.—(in the Architectural Theatre, University College, Gower Street, W.C.1).—Annual General Meeting. A. L. Leach (Presidential Address): "The Geology and Scenery of the South Pembrokeshire Coast".

ROYAL INSTITUTION, at 9.—Sir Douglas Mawson: "The New Polar Province".

Financing Research

ONE of the commonest indictments of the financial structure in Great Britain as compared with, for example, Germany and the United States of America, has been the reluctance of our banking system to make advances for the financing of new industrial enterprises or the reconstruction on modern lines of established industries. There has, indeed, existed a definite gap in our national organisation, to which the Macmillan Committee directed attention, and to close which it suggested the development of a new body or Board of National Investment. Reference has frequently been made to this gap in recent months, notably in a letter to the Prime Minister from Mr. T. D. Barlow, the chairman of the Lancashire Industrial Development Council.

The unanimity with which, at recent general meetings of various important banks, the chairmen have been at pains to stress the importance of scientific research is accordingly the more remarkable and indeed startling, while Mr. J. W. Beaumont Pease, addressing the meeting of Lloyds Bank, made the significant statement that steps to form an organisation to close this gap in our financial structure are actually being taken.

Addressing the shareholders of Martins Bank Ltd. on January 24, Mr. A. A. Paton, for example, quoted examples of successful research in the cotton industry, particularly the recent discovery of a method of treating cotton cloth chemically which renders it practically indistinguishable from silk, and said that this result was directly due to research on scientific lines undertaken in Manchester. It may well establish cotton goods as a rival both to rayon and to silk, and substantially assist our export of cotton cloth in the finer qualities. "This success," said Mr. Paton, "should encourage all industrialists to recognise the important part that scientific research can play in the development and improvement of their production and lead them to a wider realisation of its value to them."

Mr. F. C. Goodenough's address to Barclays Bank Ltd. similarly asserted that the importance of research work in the advance of industry cannot be overestimated. The place to be assigned to the scientific worker in industry is, he said, a factor of the greatest importance which we cannot afford to overlook in the production of high quality goods. We must look forward to the development both of co-operation and individual effort in research if the craftsmanship of our workmen is to receive the maximum support of scientific knowledge in facing the present severe world competition. Similarly, the Hon. Rupert E. Beckett, addressing the Westminster Bank on February 2, asserted that we must endeavour by every means at our command to keep abreast of development in existing industries and take advantage of every opportunity to establish new industries. To allow industry to mark time would be fatal. We have a great reserve of scientific and inventive ability and it is essential that, faced as we are with shrinking markets for our products in many directions, we should utilise to the full any opportunities for new development which may be made available to us by scientific investigation. Mr. R. MacKenna's address to the Midland Bank on January 27 also referred to the great attention paid by many firms to scientific research, the value of which can scarcely be overstated, "though there is still room for great advance in this direction. The facilities for such research, through Government establishments, trade organisations and university institutions are greater than ever before and should be used to the full."

In the same strain Sir Christopher Needham told the District Bank Ltd. on January 27 that "A modern competitive industry must regard industrial and technical research as a necessary part of its very structure; only then will it be ready to take full and prompt advantage of improvements which scientific discovery reveals. The benefits of research are not necessarily restricted to big business, for any concern, great or small, which is wise enough to seek it can now find the essential help of this kind at its disposal." Of the cotton industry he added, "To-day more than ever before the cotton industry needs to know all that science can discover about the raw material it uses. The industry is singularly well served by its Research Association at the Shirley Institute and this co-operative effort of the industry to apply science to the production of cotton goods has been more than justified by results." He expressed the hope that the efforts of the scientific workers and technicians will receive that encouragement and help from the industry which they deserve.

Joining in the same chorus, Mr. G. P. Dewhurst also referred to the position in the cotton industry and told the Williams Deacon's Bank Ltd. on the same day that "Facilities for industrial research are available for all and science is fully capable of showing how processes of manufacture may be improved upon and persistent investigation to that end cannot fail to bring its reward".

Sir Harry Goschen's address to the National Provincial Bank Ltd. on January 26 referred to scientific research and the application of its results in industry as being at the root of our power to sell our goods and to meet the needs of our population so far as possible out of our own resources. Slow as the practical man in Great Britain has been on the whole to take full advantage of the products of the laboratory, the greater interest he is now taking in scientific activity is a happy augury for the future welfare of our people. There is room, Sir Harry said, for still closer contact between the industrialist and the scientific worker and this is provided by that useful organisation, the Department of Scientific and Industrial Research.

Mr. J. W. Beaumont Pease's contribution, as chairman of Lloyds Bank Ltd., is sufficiently important to merit quoting in detail. Admitting that a prime condition of industrial recovery is the solution of the difficult international financial problems which confront us, he asserted that that in itself would not ensure the return of prosperity to Great Britain unless we exercise the same resourcefulness and enterprise which our predecessors showed in no less difficult though somewhat different circumstances in the past. "To-day there is probably no direction affording a better prospect of rich reward than scientific discovery. It has to be remembered that the exercise of the native and untutored genius for improvisation and invention which in the past was sufficient to keep us in the van of progress is no longer sufficient. Economic production is to-day a highly expert business requiring the specialised training such as is possessed by the man of science. We must turn more and more to the research worker to point the way towards new advances and industry must realise that an efficient and well equipped research organisation is an essential element of good management."

Referring to the facilities for industrial research which are open to all in Government establishments, trade research associations and university institutions, Mr. Pease, in answer to the argument that only the larger and richer firms can finance such research, agreed that some organisation for providing finance for intermediate loans of modest amounts, and for comparatively short periods, which would fill the gap between ordinary banking loans and those of a longer duration and for rger sums, would be a desirable ado nancial machinery. Steps to form rganisation, he announced, are actually being aken.

The scientific worker may well rub his eyes in bewilderment and wonder whether the millennium has dawned! That the chairmen of eight large banks should speak in exactly the same strain and in the course of balanced and comprehensive surveys of the national position, in which due regard was had to all the other relevant factors, can scarcely be mere coincidence. The statements regarding the position and importance of research as a factor in national and industrial development could not be bettered and represent an outlook we have consistently urged in these columns for years past. Such sudden and mass conversion of a section of the community renowned for its conservatism cannot but quicken expectations of welcome and beneficial developments in national policy.

To whatever leaven this change of outlook is to be ascribed, whether to the educational work of the Department of Scientific and Industrial Research and other organisations, to the intensity of our present difficulties, or to increased contact with those responsible for developments in Germany, the United States, or Soviet Russia, undue optimism would be premature. On one hand, research is only one factor in new industrial development and the revival of trade is indeed only one of the fields in which scientific thought makes an important if not essential contribution. On the other hand, the present precarious position of the Research Association of British Rubber Manufacturers, which was discussed in NATURE of February 11 and 25, reminds us that industry is still very far from accepting research as a fixed charge comparable with obsolescence and insurance.

Plenty of evidence could be found that in other industries also, those in control have yet to learn that there is something to be gained by the application of the results of research. In the cotton industry, more co-operation is still required between the Shirley Institute and the technical staff in the industry. The scarcity of technical men on the directorates and boards of many industries is a common obstacle to the full appreciation of the value of scientific work, and research staffs are often the first to be cut down in times of panic.

There is, however, in such unanimity as is shown by the banking interests, at least the danger that over-emphasis may be laid on the assistance which scientific research can contribute towards recovery. Research is only one factor, and a great expansion in scientific and industrial research is more likely to contribute to our future prosperity than to the relief of our immediate difficulties. What is perhaps even more important at the present moment is that greater use should be made of the results of research already available, and that the scientific spirit and method should be more seriously and widely applied to assist in the handling of those difficult and intricate problems of management, production and distribution, on a national as well as on an international scale, with which industry and politics alike are confronted in a scientific age. It is to be hoped that the scientific outlook indicated in the eight addresses we have quoted will be reflected in the banks themselves according a place to scientific and technical opinion and advice in their counsels. It is only as such steps are taken that we can hope for the appropriate handling of the difficult problems which research inevitably brings in its train. It must be remembered that, from one point of view, scientific and industrial research disturb the stability of our economic and social order. Research tends to a dynamic society the ordering of which makes much greater demands on administrative ability than are made by a static order.

That scientific research should be commended in this manner is at least an encouraging sign. We may hope that such encomium will induce industry generally to apply more wholeheartedly and widely the results of research, to accord technical and scientific men a much more influential place in the conduct of its affairs, if not indeed to demand technical and commercial attainments as essential qualifications for a place on its boards of directors and management. We may hope, too, that the changed outlook will result in far more generous support for fundamental and long-range research, whether conducted in Government institutions or in the universities, upon which in the end even industrial progress depends. There is so much room for improvement in these matters that long before excessive effort has been expended on research, scientific workers themselves should be able to bring home to the community the essential fact that research is only one factor in recovery, one aspect of the fundamental problem of ordering the life of industry and of society in the light of reason and knowledge and not of prejudice.

Radio Communications by [illegible] Short Electric Waves

THE Marchese Marconi delivered the Friday evening discourse at the Royal Institution of Great Britain on December 2 and described his experimental investigations during the past year or two with electric waves less than one metre in wave-length. The systematic investigation of the properties and characteristics of these very short waves was taken up in view of the advantages which they seemed to offer in the field of practical radio communication, on account of the small dimensions of the apparatus necessary for emitting and receiving a considerable amount of electrical energy, combined with the freedom from interference due to electrical disturbances on such wave-lengths. At the commencement of his lecture, the Marchese Marconi referred to the fact that in 1896 he demonstrated the possibilities of short-distance wireless communication on a wave-length of about 30 cm., using a 'spark' transmitter and suitable reflectors. In the more recent work, a thermionic electron oscillator was employed, operating on the principle first demonstrated by Barkhausen and Kurz as a means of producing oscillations corresponding to wave-lengths of less than 100 cm.

DEVELOPMENT OF THE TRANSMITTING CIRCUIT

After testing, with varying success, all available receiving and amplifying valves with cylindrical electrodes used in the standard circuits, a special type of valve was developed, suitable for generating powerful oscillations under conditions leading to a reasonable life. These valves were made in pairs, as the mirror images of one another, and the basic circuit developed for their use is indicated in Fig. 1.

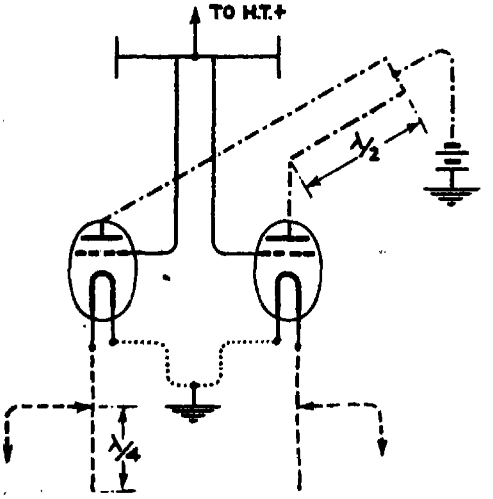

FIG. 1. Valve circuit for short-wave transmitter. Outside filament tuning - - - - ; inside filament tuning .... ; plate tuning -·-·-·- ; aerial and feeder impedance transformer ———.

This new electronic oscillator is characterised by three definite tuned circuits, namely, an inside and outside filament-tuning circuit and an anode-tuni circuit, and also by the use of a feeder-impedanc transformer, the purpose of the latter being t match the internal resistance of the valves wit that of an efficient dipole aerial. The small disc at the end of the dipole aerial act as end capacities, and experience has definitely indicated that their use secures more radiated power and renders easier the adjustment of the feeder-impedance-transformer than is otherwise possible.

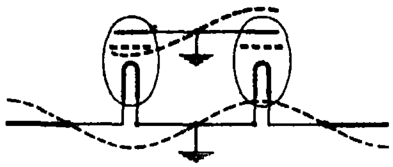

FIG. 2. Distribution of potential along filament tuning and plate tuning circuit.

The anode-tuning and the inside filament-tuning circuits are the controlling factors of the wave-length at which the transmitter can be made to oscillate with efficiency, all the other adjustments being dependent upon them. It is necessary to point out that the length of conductor required to connect the two anodes together for correct tuning is very small—it is only about 5 cm. for a wave-length of the order of 50 cm.—and the explanation of the fairly long kind of Lecher wire, shown in Fig. 1, is that it has been found possible and also desirable to add to that short conductor another conductor one wave-length long, bent back on itself to avoid loss by radiation.

The correct distribution of the potential along the plate and filament circuits, obtained by these tunings, is shown in Fig. 2. In addition to adjusting correctly all the external portions of the new circuit, it is necessary to arrange the electrical supplies to the valves employed so as to generate electronic oscillations between their electrodes at a frequency corresponding as closely as possible with that of the external circuits.

The radiated energy of one standard unit transmitter has been measured by placing the whole apparatus, except the aerial and feeder, in a calorimeter and taking temperature curves first with the transmitter in oscillation, and then in non-oscillating condition, all the electric currents being kept constant. Consistent results were obtained by this method indicating an average radiation power of 3·5 watts. The power absorbed by the filament was approximately 30 watts, that by the grid approximately 25 watts, the overall efficiency being, therefore, about six per cent, increasing to fourteen per cent, if the grid power only be taken into account.

The possibility of substantially increasing the radiating power of a transmitter was successfully realised by running several of these unit transmitters in parallel with their aerials all in line and spaced so as to secure the maximum directive effect.

Various methods of modulating the new transmitter were investigated, and the one finally adopted, chiefly on account of its simplicity, was that of superimposing the modulation on the steady negative bias voltage applied to the valve anodes. Where several transmitting units were connected together in correct phase, the anode circuits were connected in parallel and were thus modulated simultaneously. The anode-filament impedance of a unit transmitter has been measured and found to be about 2,500 ohms, and this value has been used in designing the modulating transformer.

WAVE-LENGTH MEASUREMENT

During the investigations, a practical form of wave-meter and radiation indicator was developed consisting of a dipole aerial provided with large discs to form end capacities. A standard type of thermo-milliammeter of low internal resistance was connected at the centre point of this aerial to indicate resonance with the radiated field from the transmitter. Wave-lengths of the order of 60 cm. could be measured to about 1 mm. by coupling the meter to an ordinary Lecher wire system, which, when in tune, reduced the oscillation in the meter to zero. After calibration in this manner the indicator was employed to adjust the transmitters to the working wave-length. In the case of the transmitters already described, it was found that by adjusting the external circuits and the electrical supplies, the standard valves were capable of generating oscillations at practically constant efficiency over a continuous range of wave-lengths of 80–50 cm. With the aid of other valves having smaller and shorter electrodes, a continuous wave-length range of 55–35 cm. could be covered at about the same efficiency.

REFLECTOR ARRANGEMENTS

The idea of utilising a system of unit reflectors followed logically on that of the system of unit transmitters just described. The advantages inherent in the possibility of placing side by side several transmitter units working in phase with each other for the purpose of increasing the power of a transmitting station, would, in fact, have been partly lost if the same method could not have been extended to the reflector.

Considering the type of multi-unit transmitter developed, it was decided to adopt the ordinary well-known cylindrical parabolic reflector, on the design of which a considerable amount of experience was already available. The high efficiency observed by experimenting with these very short waves with free end reflector rods in place of wires or rods supported at each end by insulators, leads to a peculiar type of construction where each reflector rod is supported at its middle point by a copper tube bent into a true parabolic curve.

The accompanying photograph (Fig. 3) illustrates the type of reflector adopted; this is economical in construction and has an important advantage in offering a small wind resistance. This system comprised four reflector units side by side, the aperture being three wave-lengths, and the focal length one quarter of a wave-length. The reflector rods were excited by three unit transmitting aerials, arranged along the focal line of the parabolic cylinder. Each transmitting aerial was located so as to overlap two adjacent reflector systems, this arrangement facilitating the correct phasing of the several transmitters. In this manner a directional transmitting system was provided in which the radiated energy concentrated in the forward beam was about 17 decibels above (about fifty times) that given by a half-wave dipole aerial alone.

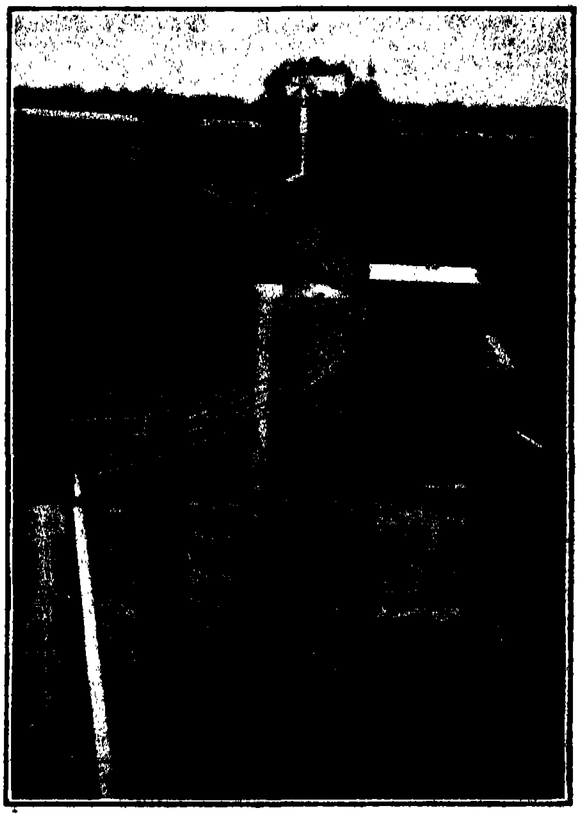

FIG. 3. Reflector system.

RANGES OBTAINED FOR PRACTICAL COMMUNICATION

After developing suitable receivers for the very short wave-lengths involved, a number of short-range communication tests were carried out during October and November, 1931, at distances of 11–23 miles oversea. In April 1932, a demonstration of duplex communication was given with equipment incorporating ordinary two-wire telephone terminal apparatus. This demonstration showed the practicability and resulting advantages of working both transmitter and receiver in the same reflector, and satisfactory two-way communication was maintained for several hours over the distance of 23 miles. Soon after this demonstration, the Vatican authorities decided to adopt this system for telephonic communication between the Vatican City and the Palace of the Pope at Castel Gondolfo, near Rome. The distance between these two points is more than twelve miles entirely overland, and the direct line between them is obscured by intervening trees. The apparatus has now been installed, however, and is giving satisfactory operation on what constitutes the first commercial radio link on a wave-length of less than one metre.

For the purpose of carrying out long distance tests, a more powerful transmitter was developed, comprising a five-unit reflector with a four-unit transmitter. A standard receiver with single reflector unit was installed on the yacht *Elettra*, and after preliminary tests over distances up to 28 miles, preparations were made for tests over longer ranges. The transmitting equipment was installed in an obsolete observatory at Rocca di Papa, near Rome, at a height of 2,500 ft. above sea-level and about fifteen miles inland. Under these conditions the maximum optical range as set by the curvature of the earth, for a rectilinear path between transmitter and receiver, was 52 miles.[*] In August 1932, duplex communication was established on a wave-length of 57 cm. between this station and the yacht at a distance of 18 miles. Satisfactory communication was continued at distances up to 58 miles, beyond which the signals became subject to slow and erratic fading, although they were still perceptible up to a distance of 110 miles.

After a repetition of the above test, in which the maximum range of perceptible signals was 125 miles, the receiving apparatus was installed on Cape Figari, Sardinia, at an altitude of 1,100 ft. above sea level. The distance between Rocca di Papa and Cape Figari is 168 miles whilst the optical distance, taking account of the heights of the two places, is only 72 miles.[*] When tested under these conditions, signals were immediately received from the transmitter, although they were subject to the same slow deep fading observed on the yacht. Excellent intelligible speech was received during the strong periods of the signals, but these became practically inaudible during the weak periods. This test lasted from about 4 P.M. until midnight, and the average signal strength appeared to be greater before than after sunset. On investigation at Cape Figari, it was found that the waves were arriving from a horizontal direction.

In conclusion, it may be said that these investigations serve to illustrate some of the practical possibilities of the application of electric waves, less than one metre in wave-length, in the field of radio communication. R. L. S.-R.

---

[*] These values for the optical range, as given by the Marchese Marconi, do not appear to be correct. For the height of transmitter given, the range to sea-level is about 63 miles, while to the receiver at the height stated above, the optical range is 105 miles. It may also be pointed out here that ranges in excess of the optical distance have previously been obtained for radio telephonic communication on wave-lengths between 5 and 8 metres (see *Proc. Inst. Radio Eng.*, 19, 485, 1825, 1931).

Humour and Humanism in Baeyer's Laboratory

PROF. H. RUPE entered the private laboratory at Munich, as assistant to Baeyer, in 1891. At that date the great indigo problem had been solved, but the classical work on the reduction of the phthalic acids was still in full swing. These investigations, so well known in the abstract because of their bearing upon the constitution of benzene, take on at once a rich vesture of human interest to the reader of Prof. Rupe's delightful reminiscences of life in Baeyer's laboratory which have recently been published[*]. The work was beset with difficulties. At one time, for example, during the intensive search for dihydrophthalic acids, gigantic quantities of sodium amalgam, up to forty kilograms a week, were prepared and used in vain. The author remarks with feeling that the situation became very disagreeable to the assistants. It must have been, indeed, a "schwere, scheussliche und gefährliche Arbeit"; but no labour was too tedious for the Master and his band of devoted helpers. There was, as Prof. Rupe says, something of the magnificent in this prolonged contest with matter.

Eventually, however, even Baeyer was supersaturated with these hydrogenations ("übersättigt von diesen Hydrierungsarbeiten"), and the sorely tried assistants hailed with deep relief the transference of his interest to succinylosuccinic ester and diketocyclohexane. By means of a 'Kunstgriff' of which Baeyer was very proud (treatment with sodium amalgam in presence of sodium bicarbonate), the diketone was reduced to quinitol. At the first glimpse of the crystals of the new substance Baeyer ceremoniously raised his hat!

It must be explained here that the Master's famous greenish-black hat plays the part of a perpetual epithet in Prof. Rupe's narrative. As the celebrated sword pommel to Paracelsus, so the 'alte Melone' to Baeyer: the former was said to contain the vital mercury of the medieval philosophers; the latter certainly enshrined one of the keenest chemical intellects of the modern world. Hats are not associated as a rule with chemical research, although it is true that Trautschold's illustration (1842) shows the striking variety of headgear which was to be seen in

---

[*] Adolf von Baeyer als Lehrer und Forscher: Erinnerungen aus seinem Privatlaboratorium. By Hans Rupe. (Sammlung chemischer und chemischtechnischer Vorträge, herausgegeben von Prof. Dr. H. Grossmann, Neue Folge, Heft 15). Pp. 26. (Stuttgart: Ferdinand Enke, 1932.) 2.50 gold marks.

Liebig's original laboratory at Giessen: these choice pieces, although perhaps not including an 'alte Melone', ranged from the postman's cap of Ortigosa the Mexican through the tam-o'-shanter of his unnamed neighbour to the stylish topper favoured by A. W. Hofmann. It now appears that the tradition of laboratory hats descended from Liebig to Baeyer. However that may be, Baeyer's head was normally covered. Only in moments of unusual excitement or elation did 'the Chef' remove his hat: apart from such occasions his shiny pate remained in permanent eclipse.

When, for example, the analysis of the important diacetylquinitol was found to be correct, Baeyer raised his hat in silent exultation. Soon afterwards the first dihydrobenzene was prepared, by heating dibromohexamethylene with quinoline: Baeyer ran excitedly to and fro in the laboratory, flourishing the 'alte Melone' and exclaiming: "Jetzt haben wir das erste Terpen, die Stammsubstanz der Terpene!" Such is the picture from behind the scenes of the dramatic way in which the Master entered upon his famous investigations on terpenes.

Incidents of this kind may appear to be slight, and yet cumulatively they throw a stream of light upon the personality of this great chemist. There is no doubt, for example, that at times 'the Chef' was unduly impulsive. One morning he burst into the private laboratory, and, without having lit his cigar (an indication in itself of unusual emotional disturbance), raised the ancient 'Melone' twice, and exclaimed: "Gentlemen [the audience was composed of Claisen and Brüning], I have just had word from E. Fischer that he has brought off the complete synthesis of glucose. This heralds the end of organic chemistry: let's finish off the terpenes, and only the smears ('Schmieren') will be left!" Prof. Rupe's reminiscences are rich in snapshots of this kind, which are often more revealing than pages of formal description could be.

Baeyer's customary tools were test-tubes, watch-glasses, and glass rods. As an example of his endless patience, Willstätter relates having seen him keep a test-tube in gentle play over a flame for three-quarters of an hour when activating magnesium with iodine. He valued at least three things which were deemed of fundamental importance by the alchemists; for he impressed upon his students that the essential attributes of the chemist are patience, money, and silence. His lectures were marked by clearness and simplicity of diction, with occasional delicate touches of North German humour or sarcasm. He urged his listeners to learn to think in terms of phenomena; and, like Kekulé, he emphasised the importance of giving occasional rein to the imagination: "so viele Chemiker haben nicht genügend Phantasie".

Although 'the Chef' was often regarded as stiff, unapproachable and severe, he was in reality a kindly man who did much good by stealth. He was free from vanity; and, unlike many men of learning, he was always ready to acknowledge ungrudgingly the merits of others. Baeyer favoured the use of simple apparatus, and the introduction into his laboratory of any device savouring of complexity had to be undertaken with great tact. The first mechanical stirrers, worked by water-turbines, were smuggled in one evening. On the following morning, 'der Alte' beheld them in full working order. For a time he affected to ignore them; then he contemplated them unwillingly, with an air of challenge; next came the first remark, so anxiously awaited: "Geht denn das?" "Jawohl, Herr Professor, ausgezeichnet, die Reduktionen sind schon bald fertig." The Herr Professor was finally so much impressed that he took the exceptional step of summoning the Frau Professor. 'Die Lydia,' as she was called in the laboratory, stood by the merrily clattering apparatus for a while in silent admiration; then she uttered these unforgettable words: "damit müsste man gut Mayonnaise machen können"! What a great deal depends upon one's point of view!

These truly fascinating pages afford glimpses also of the personnel surrounding 'the Chef'. Among them, Herr Leonhard, the old Bavarian factotum inherited by Baeyer from Liebig, stands out by reason of his liberal attitude towards the ethics of lecture demonstrations. Upon occasion he triumphed over his scruples to 'help' his experiments in their fight against the malignity of matter ("Tücke des Objektes")—that bane of the whole race of lecture-assistants: as witness his dry reply to a remark upon the difficulty of making chloroform from alcohol and bleaching powder: "Wissens Herr Doktor, dös Chloroform, dös is schon do herinnen"! There was also the old 'Laboratoriumdiener', Carl Gimmig, a veteran zouave of the war of 1870, with his compelling six-o'clock cry: "Ihr Herre, s'isch Zeit!" If the workers lingered, Carl remorselessly turned off the gas at the main and became 'terribly evident'. There is, too, an instantaneous snapshot of a 'filia hospitalis' of the laboratory, the fair daughter of Herr Inspektor Fehl; but of her it may be said, as of her prototype in the song so beloved of German studentry, that "die Füsschen laufen wie der Wind" off Prof. Rupe's pages.

A narrative of this kind cannot fail to reflect something of the personality of the author, and in the concluding relation of the surreptitious help he once extended to a would-be pharmacist, overcome with 'Examenangst' (expressive word!) in Baeyer's 'Bleikammer', we obtain a glimpse of Prof. Rupe's innate kindness of heart.

"Chemistry has always seemed to me such a *dead* subject—so utterly devoid of human interest!" exclaimed a classicist within the hearing of the present writer the other day, as he stepped somewhat reluctantly into a lecture on alchemy. May he and others who share that mistaken view seek a truer orientation in this matter from such writings as these sparkling reminiscences of life and labour in the laboratory of Adolf von Baeyer.

JOHN READ.

Obituary

SIR J. ARTHUR THOMSON

WITHIN two years of his retirement from the chair of natural history at the University of Aberdeen, Sir J. Arthur Thomson was struck down by a heart illness which had hampered his well-being for many years, and although he rallied, his power of resistance was broken and he died at his home at Limpsfield in Surrey on February 12, aged seventy-one years.

Born at Saltoun, East Lothian, on July 8, 1861, a son and grandson of the manse, Thomson graduated M.A. at the University of Edinburgh in 1880, and thereafter completed the divinity course at New College. But the influence of his teachers, and a natural bent derived from two generations of naturalists on his mother's side, swung the balance towards the study of natural science, and in 1883 he was at Jena under the guidance of Ernst Haeckel, and in 1885 with Schulze at the Zoological Institute in Berlin. He returned to Edinburgh to become the most popular teacher of his time in zoology and botany, and his success there led to his appointment in 1899 to the regius chair of natural history at Aberdeen. He was a good teacher, clear and sympathetic, never losing sight of the wood for the trees, insistent upon the broad truths to which the facts pointed; and so during these thirty-one years he kept turning out a stream of scientific workers remarkable in its volume for a small university recruited from schools where biology is unknown.

At the same time, Thomson was constantly engaged upon systematic investigations of the Alcyonaria, collections of which came to him for identification from almost all the seas of the world. The majority of his papers upon these collections were included in the reports of special expeditions, so that the mass of his descriptive work has been scarcely recognised; but although it was perhaps the least important of his great activities, it was very far from being negligible, as is witnessed by the extent of the collection of type and named specimens he presented to the British Museum on his retirement, and by the excellence of such memoirs as his accounts of the Alcyonaria of the Australian *Thetis* Expedition, of the Prince of Monaco's collection, and of the Dutch *Siboga* Expedition to the East Indies, the last of which appeared not many months ago.

Apart from his teaching, Thomson's great achievement was undoubtedly as an expositor of science and scientific thought. He had a gift of simple, lucid writing and lecturing, which enabled him from his full knowledge to expound the beauty and interest of Nature, so that no man of his time has done so much to interest the people in natural history. That was a work of importance, paving the way for that appreciation of scientific work which will allot to it its proper place in the life and progress of civilisation. He was in demand at home and abroad as a lecturer, and his lectures in book form, together with his other writings, make a considerable library in themselves. They were by no means all of the popular sort, and amongst the best I should be inclined to place "The Evolution of Sex" (1889) written with Patrick Geddes, "The Science of Life" (1899), a neat summary of biological progress, "The Wonder of Life" (1914), the St. Andrews Gifford lectures "The System of Animate Nature" (1920), the "Biology of Birds" (1923), and his last great work, written again with Geddes, "Life: Outlines of General Biology" (1931), a store-house of biological themes. On the popular side, the larger works which were probably most widely read were "The Outline of Science" which he edited and mostly wrote, and "The New Natural History".

Many honours came to Sir Arthur: he was invited to give several important series of lectures in Great Britain, in South Africa and America; he was created a knight on retirement from his chair, and then also Aberdeen made him an LL.D., a degree which had already been conferred upon him by his own University of Edinburgh, and by McGill University and University of California. Throughout it all he preserved a charmingly simple, almost shy demeanour, which hid a warm heart and much friendliness.

Sir Arthur Thomson could not have accomplished his vast output without the active assistance of Lady Thomson, herself a naturalist, and it is evidence of the strength of heredity and of the influence of early nurture, that each of the members of their family, three sons and a daughter, has contributed to scientific literature.

JAMES RITCHIE.

PROF. A. H. SAYCE

WITH the passing of Archibald Henry Sayce on February 4, Oxford loses one of the last, if not the last, of the old life-fellows, and the world a link with the scholars, of whom Sayce was by no means the least, who first deciphered the languages of the inscriptions of the old tongues of Mesopotamia and the surrounding regions, and so put on a firm basis the study of the ancient history of the Nearer East.

Sayce was in many respects a most remarkable man. He was born so far back as 1846, the oldest son of the Rev. H. S. Sayce, vicar of Caldicot, Mon., and even in undergraduate days had the misfortune to have bad health, but he was endowed with a remarkable persistence, and a scarcely less remarkable memory. He found the handling of heavy texts, lexicons and dictionaries an unpleasant task, and certainly for very many years abandoned their use, preferring to quote, not always perhaps accurately, from his well-stored memory. It is perhaps to this fact that we owe the enormous breadth of his learning, for he remembered all he read and up to the very last was reading and annotating with many linguistic parallels the latest current periodicals. He always moved with the times.

Sayce's early interests were mainly of a philological nature, including not only technical work on ancient languages, but also services to the revisers of the Old Testament, and a text and commentary on Herodotus. Later, he turned to questions of comparative religion, and when he was already more than sixty years of age, pure archæology especially attracted him. He acquired a very complete knowledge of modern work on prehistoric archæology, and the present writer remembers discussing with him, in his eightieth year—and it was Sayce who did most of the discussing—the problems of Mousterian and Upper Palæolithic flints in Transjordan. The geographical and scientific side of Assyriology was always of great interest to him, possibly owing to his early training under the Rev. Bradford Waring Gibson of Trinity College, Cambridge, a keen student of mathematics who was headmaster of Grosvenor College, Bath, where Sayce was educated. Unfortunately, apart from such publications as his "Notes on an Unexplored District of Northern Syria" in the *Proceedings of the Society of Biblical Archæology* of 1911, most of his geographical work is buried in former editions of the "Encyclopædia Britannica".

In addition to these wide interests, Sayce was an admirable preacher, and a pleasant and witty companion even to those widely separated from him in years, and it is sad to think that he no longer occupies the rooms in Queen's which he has had since he first became a fellow, nor shall we see any more the frail figure of our old friend walking along the sunny side of the Banbury Road on his way to visit one of his many pupils, for so we were, though he never gave and, indeed, of later years disliked, formal teaching.

Sayce obtained a first-class both in Moderations and Greats, taking his final Schools in 1868, a year which included Andrew Lang, E. A. Knox, afterwards Bishop of Manchester, T. Humphrey Ward, and K. A. Muir-Mackenzie. He obtained his fellowship in 1869, and was classical and theological tutor from 1870 until 1879. He was a member of the Old Testament Revision Company from 1874 until 1884, and deputy professor of comparative philology from 1876 until 1890; in the following year he became professor of Assyriology, and resigned in 1914. In 1897 he became president of the Society of Biblical Archæology, and retained this position until the Society was amalgamated with the Royal Asiatic Society in 1918. He was Hibbert lecturer in 1887, Gifford lecturer in 1902, when he discussed "The Conception of the Divine among the Egyptians and Babylonians", Rhind lecturer in 1907 and Huxley lecturer of the Royal Anthropological Institute in 1930. His honours were naturally mainly academic. His old University made him an Hon. D.Litt. in 1907, he was an honorary fellow of the British Academy and Hon. LL.D. of Dublin, and also held the honorary degree of D.D. at Edinburgh and Aberdeen.

It is not possible to recount Sayce's many publications. His first publications were Assyrian grammars; in 1874 he published "Principles of Comparative Philology" and six years later "Introduction to the Science of Language". Perhaps his best-known work is "Fresh Lights from the Monuments" which passed through no less than nine editions between 1883 and 1895, while his standard book on the Old Testament was "'Higher Criticism' and the Verdict of the Monuments" (1894). This does not include a host of other books and articles, some of which have been mentioned above, for, during his long working life, scarcely a year passed without an important contribution from his pen dealing with some aspect of Assyriology. L. H. D. B.

MR. T. A. COWARD

THE sudden death from heart failure of Thomas Alfred Coward at his home at Bowdon on January 28 leaves a gap in the ranks of British field naturalists and came as a blow to those who knew and loved him.

Coward was born in Bowdon, a Cheshire suburb of Manchester, in January 1867, and there he spent his life. Educated at Brooklands School, Sale, and Owens College, Manchester, he endured nineteen years in the uncongenial atmosphere of a Manchester warehouse, until the absorption by one of the large industrial combines of the firm which he was serving gave him the chance he craved, and for more than thirty years he was able to follow his own bent in studying animals, particularly vertebrates, in the field. He contributed occasional notes and papers to the *Proceedings of the Zoological Society*, to the *Zoologist*, *British Birds* and other more or less technical magazines. Articles in the *Field* and other newspapers and in the *Nineteenth Century* appealed to a larger public, and as "T. A. C." of the *Manchester Guardian* he was widely known.

Of Coward's many books on topography and natural history, the most serious contribution to scientific literature was perhaps the "Vertebrate Fauna of Cheshire and Liverpool Bay" (1912), which ranks high among county faunas, but better known is his "Birds of the British Isles and their Eggs", first issued in 1919, a household word among amateur ornithologists, which has done more to promote and encourage the intelligent study of birds in Great Britain than any other work of our time. To study birds he went to many out of the way parts of Britain from the Shetland Isles to Cornwall, and with his wife, who shared his tastes, visited Holland, the Camargue, the Pyrenees and Hungary in order to find birds he could not see at home.

What Coward wrote was always good reading. It was mostly the outcome of his own wide and varied experience, was free alike from technicalities and rhetorical frippery, and above all was accurate. He had a considerable vogue as a lecturer and his lectures and broadcast talks were compact of the same sound material as his writings. For more than a quarter of a century he was a distinctly educative force.

During the War, Coward was acting keeper of the Manchester Museum, and in 1921 the University conferred upon him the degree of M.Sc. in recognition of his services in that capacity. He was an active member of the Museum Committee, and devoted much time to the arrangement and care of the Dresser collection of birds. He was a member of the executive committee of the Lancashire and Cheshire Fauna Committee, and acted as referee for vertebrates. He was president of the Manchester Literary and Philosophical Society in 1921 and 1922 and a fellow of the Zoological and Entomological Societies.

C. O.

Mr. Henry A. Fleuss

We regret to announce the death on January 4, at the age of eighty-two years, of Mr. Henry Albert Fleuss. He was one of the pioneers of rescue apparatus. After serving in the mercantile service for many years, he left it about 1879, in order to make a pipeless diving apparatus. He designed a suitable pump for compressing oxygen and made his first test in a tank at the old Polytechnic in Regent St., London. Without any previous experience of diving, he remained under water for one hour, which at that time was an amazing performance.

Fleuss claimed to be the first man to breathe pure oxygen without any ill-effects. At the request of Sir B. W. Richardson, he went into a chamber filled with a gas that meant death in one minute if inhaled, and stayed in there for half an hour. Later, during a lecture given by Sir B. W. Richardson, Fleuss remained in a chamber through which a current of carbon dioxide was made to flow.

Fleuss then turned his attention to mine rescue apparatus and carried out experiments at the Netherseal Colliery and Seaham Colliery. His next exploit was during the building of the Severn Tunnel, the workings of which became flooded. Fleuss went down a shaft 200 ft. deep with 40 ft. of water at the bottom, and was given up for dead a long time before he returned to the surface. The celebrated diver Lambert then put on the dress and was able to close the necessary doors to enable the tunnel to be pumped out. Messrs. Siebe, Gorman and Co., Ltd., afterwards put the apparatus on the market.

Among Fleuss's other inventions was the well-known 'Geryk' vacuum pump. He claimed to be the inventor of the first mechanical high efficiency vacuum pump ever made, in 1885. About 1890 at a demonstration at the Royal Institution an electric lamp bulb was exhausted with a 'Geryk' pump, and the lamp burned for about 1,000 hours.

Fleuss also invented a tubeless pneumatic tyre which was in great demand about thirty-five years ago.

W. G.

Dr. Willy Merck

We regret to learn from the *Chemiker-Zeitung* of the death on December 15 of Dr. Willy Merck, a member of the well-known firm of chemical manufacturers, E. Merck of Darmstadt. Dr. Merck, who was born in 1860 at Darmstadt, was the son of Dr. Georg Franz Merck, the discoverer of papaverine. After studying at the Universities of Heidelberg, Strasbourg and Kiel and at the Polytechnic at Aachen, he graduated at Kiel in 1886, where he had worked under the direction of Ladenburg. His thesis embodied the results of his studies on cocaine and he had been able to effect a partial synthesis of this alkaloid by the methylation of benzoylecgonin, a by-product obtained during the extraction of cocaine. Many years later, the complete synthesis of naturally occurring *l*-cocaine and of *d*-pseudococaine was carried out in the Merck laboratories by W. Merck in collaboration with R. Willstätter.

Immediately after his graduation, Merck entered the service of the firm and, after a year's travel in the Far East, he returned to Darmstadt to undertake a leading part in directing the work not only in the laboratories but also in the factory, where he successfully initiated the manufacture of many new drugs. In 1905 the University of Halle conferred upon him an honorary doctorate in the Faculty of Medicine and he was the recipient of many public honours and decorations. He was made *Geheimer Kommerzienrat* in 1918 on the occasion of the two hundred and fiftieth anniversary of the foundation of the firm.

The death on February 5 is announced of Mr. J. J. F.-X. King, aged seventy-seven years, one of the best-known Scottish entomologists. Mr. King was an accomplished field naturalist and collector, and some few years ago he presented his main collection of British insects to the University of Glasgow. The University is now to receive under his will the portrait of Mr. King painted by Forrester Wilson and the remainder of his collections, together with his library of books on natural history.

We regret to announce the following deaths:

Dr. C. A. Barber, C.I.E., lately lecturer in tropical agriculture at the University of Cambridge, formerly Government Botanist, Madras and Sugar Cane Expert for India, on February 24, aged seventy-two years.

Sir Benjamin Gott, chairman of the Commission on Educational and Cultural Films, who was secretary of the Middlesex Education Committee from 1898 until 1928, and formerly headmaster of the Cheltenham School of Science, aged sixty-seven years.

Prof. Johannes Schmidt, director of the Carlsberg Physiological Laboratory, Copenhagen, a leader of several deep-sea expeditions, and known especially for his work on the life-history of the eel, aged fifty-five years.

News and Views

The Pepys Tercentenary

ON February 23 the tercentenary of the birth of Samuel Pepys was commemorated in London and at Cambridge. The London celebrations included a lecture by Mr. E. Chappell arranged by the Society for Nautical Research at the Clothworkers' Hall; an address by Mr. A. Bryant to the Women's Section of the London Municipal Society at Admiralty House, and a commemoration service at the Church of St. Olave, Hart Street, where Pepys was buried and close to where he lived and worked. The service was attended by the Lord Mayor and sheriffs of the City of London and the address was given by Prebendary Wellard, chaplain to the Pepys Club. During the service a wreath was placed on the Pepys monument. At the meeting of the Royal Society in the afternoon, the fellows stood in silence as a tribute to the memory of Pepys, and the president, Sir F. Gowland Hopkins, recalled that they met on the actual date of Pepys's birth, three hundred years ago. Though Pepys, he said, was not an investigator, it was clear his business acumen and his general interests in their problems had put him high in the estimation of his contemporaries, as he was thrice elected to the council and ultimately to the presidential chair. The references in his "Diary" to the Society showed his appreciation of the privileges of a fellow and his interest in the Society's work. The commemoration at Magdalene College, Cambridge, was attended by Sir John Simon, who proposed "The Immortal Memory of Samuel Pepys".

Samuel Pepys and the Royal Society

IT was recorded in NATURE of February 18, p. 229, that Pepys, after an interval of non-service, re-entered the council of the Royal Society at the anniversary meeting on November 30, 1681, Sir Christopher Wren being president. At the anniversary meeting in 1684, Pepys became the Society's president, and it is of interest to note the frequency or otherwise of his attendances at council meetings, or at the general gatherings afterwards in Gresham College, for discourse, or for experimental purposes of the kind then possible. When presiding at councils Pepys did not always remain for these later meetings, and the reason may doubtless be found in his numerous public duties, but, as substitute, Dr. Gale, Sir John Hoskyns, Dr. Lister, and Sir Joseph Williamson were often called upon in turn. Pepys was not present at the Society's meeting on December 3, 1684, but he attended the council on December 10, as well as presiding at the subsequent meeting of fellows. From the following January 7, until September 18, he attended three councils and one meeting. He was continued on November 30, 1685, in the presidency for another year, and during that period he attended eight council meetings and three ordinary meetings. On November 30, 1686, the Earl of Carbery was made president, and Pepys a vice-president. Opportunity may here be taken to record that Sir Anthony Deane, the eminent ship designer, and co-adjutor of Pepys in naval matters, who was made a fellow of the Society in 1681, was elected to the council on November 30, 1682. At the anniversary of 1684, when Pepys became president, Sir Anthony Deane re-entered the council; thus the two were colleagues. We may, perhaps, believe that Deane owed his entry to Pepys's recommendation.

Number 60 in Time Measurements

A CORRESPONDENT has sent an inquiry as to the origin of the division of a day into twenty-four hours, each divided into sixty minutes, and these into sixty seconds. The preliminary observation may be made that the numbers five and twelve are both marked out naturally by the fingers on our hands and the months in the year; it is not surprising that their product should be selected as a convenient number. Sixty is also twice the number of days in a month, the length of the average lunar month being a little less than thirty days, and that of the average solar month a little more than thirty. John Williams, on p. 17 of his "Chinese Observations of Comets", describes the Chinese reckoning of time by cycles of sixty years and smaller cycles of sixty days, the same system of names being used for the individual years and days of a sixty-fold cycle. Possibly they used the divisor sixty again in forming smaller time-intervals. It is, however, probable that our present subdivisions of time are derived from countries less remote than China. The independence of ancient China from western nations is shown by the completely different division of the stars into constellations that was adopted there.

DR. J. K. FOTHERINGHAM gave some details of the divisions of time in use in ancient Mesopotamia at the November meeting of the Royal Astronomical Society (*Observatory*, December 1932). There were twelve months, each of about thirty days, in an ordinary year. The Sumerians divided a day into twelve *beru*, each *beru* into thirty *uš*, thus following the analogy of months and days; incidentally, this gives the origin of the division of the circumference of a circle into 360°, or twelve signs of 30° each. Dr. Fotheringham states that the Babylonians afterwards divided day and night each into twelve hours, which changed in length with the seasons. The Egyptians also followed this arrangement. Moreover, sixty was an important number in the Chaldean system of numeration, so that it was natural to use it in subdividing the hour into sixty minutes, and, at a later date, in dividing the minute into sixty seconds. The latter unit was unimportant until fairly accurate clocks had been constructed.

Gift to Herbarium of University of Bristol

MR. J. W. WHITE, the Bristol field botanist, who died on October 26 last, bequeathed the whole of his British and Continental herbarium and a hundred valuable books to the Botany Department of the University of Bristol. The whole herbarium is made up of about 15,000 sheets of which those carrying British species occupy six, and those carrying Continental European species occupy fifteen large cabinets. Most of the plants in this herbarium were collected by White himself on his walks and travels at home and abroad, but numerous additions have from time to time been made by exchange and purchase. The specimens are beautifully mounted, well labelled, carefully catalogued and useful notes and relevant cuttings are frequently attached to the sheets. White was the author of "The Flora of Bristol", published in 1912, which is rightly considered a model of what a county flora should be. His herbarium is, however, of far more than merely local importance. The accuracy and critical nature of his determinations make it of real scientific value and wide general interest. By coming into possession of this herbarium the *hortus siccus* of the University of Bristol has become one of the four best-equipped university herbaria in England.

Verulamium, 1932

EXCAVATIONS at St. Albans in 1932, of which Dr. and Mrs. R. E. Mortimer Wheeler gave an account at the Society of Antiquaries on February 23, have again added to the impressiveness of the prehistoric site and enhanced its importance as a source of knowledge of conditions in Britain immediately before the Roman invasion. The chance discovery in 1932 of a hoard of silver coins a mile north of the Abbey in the dyke running across country from the north of St. Albans in the direction of the village of Sandridge, not only proved the existence of the dyke before the second century A.D., but also led to the determination of the true character of this remarkable work, which is 100 ft. broad, 30–40 ft. deep and some five miles long, as a British defensive work extending from the pre-Roman city at the south-west of St. Albans to prehistoric works, of which the remains are still to be seen at Wheathampstead. Excavations here in the past summer have shown this to be a prehistoric 'city' about a hundred acres in extent, the most remarkable of its kind in the period yet found in Britain. It would appear that this great work was constructed by the Belgic invaders of Britain, who established their headquarters at St. Albans towards the end of the first century B.C. In his account of the past year's exploration of the Roman city, Dr. Wheeler drew a gloomy picture of the social and economic depression, alleviated only by a brief and illusory recovery, which invaded Verulamium as Roman power declined, after a brilliant and perhaps too optimistic efflorescence of prosperity. In the juxtaposition of pre-Roman and Roman on an extensive scale and in the evidence of the varied fortunes of a prolonged Roman occupation, St. Albans, under continued exploration, promises to become one of the most instructive and impressive archæological sites on the fringe of the Roman Empire in the western world.

Federal Council for Chemistry

IN its report for 1932, the Federal Council for Chemistry refers with regret to the necessary postponement of the ninth International Congress of Pure and Applied Chemistry and the eleventh conference of the International Union of Chemistry, which were to have been held in Madrid in 1932. The next meeting of the Union will take place in the spring of 1934 in Madrid, and not in Switzerland, as previously arranged. During the year, the Verein Oesterreichischer Chemiker and the Svenska National Kommitten för Kemie were elected members of the International Union. The report refers to a conference on chemical documentation, held in Paris in October 1932, and indicates that the Federal Council and the Division of Chemistry and Chemical Technology of the U.S. National Research Council are in complete agreement with regard to certain criticisms of the activities of the International Committee dealing with the reform of biochemical nomenclature. The efforts of the British Standards Institution to extend the use of the words "British Standard" to include "chemical substances used in manufactures, photography, or philosophic research and anti-corrosives" were supported by the Federal Council. The Board of Trade agreed to the Institution proceeding with an application to register provided that it was in a position to submit support from the appropriate trade association or similar body. A significant passage in the report is as follows: "In October, a Committee consisting of Dr. E. F. Armstrong, Mr. E. R. Bolton, Dr. L. H. Lampitt, Prof. G. T. Morgan, Mr. Emile Mond, Prof. J. C. Philip, Sir William Pope, Mr. J. Davidson Pratt, and Mr. D. Rintoul was appointed 'To consider how the resources of the various bodies concerned with the professional and scientific welfare of chemists can be most economically and efficiently utilised'. This Committee has met on several occasions, and will present, early in 1933, a report on its findings for consideration by the Federal Council." We shall look forward with interest and expectation to the outcome of the deliberations of so representative a committee, which is dealing with a matter of national as well as professional importance.

Photographic Analysis of Explosion Flames

AT the Friday evening discourse at the Royal Institution on February 24, Prof. W. A. Bone discussed "The Photographic Analysis of Explosion Flames". Nowadays the photographic analysis of explosion flames has become an indispensable part of the scientific study of explosions. Prof. Bone described first, with experimental illustrations, how the earlier work of Mallard and Le Chatelier and of Berthelot and Vieille in France, as well as that of H. B. Dixon and his collaborators in Great Britain, during the period 1883–1903, revealed, not only the successive stages in gaseous explosions, but also much about the nature of the final phase of 'detonation' (*l'onde explosive*) with its intensive chemical action, high constant velocities (one or two metres per second) and shattering effects. Prof. Bone then dealt principally with recent developments in the designing of high-speed cameras by Mr. R. P. Fraser at the Imperial College, South Kensington, where it has now become possible not only to photograph, but also to analyse with precision, periodic movements in explosion flames occurring with frequencies up to a million a second. A number of the resulting photographs were exhibited showing the influence of compression waves in accelerating explosion flames and setting up detonation therein and, more particularly, the new phenomenon of 'spin' in detonation, which is due to a highly luminous comet-like 'head' of detonation spiralling through the medium with a frequency of several tens of thousands a second, and appears to be a concentrated locus of positively charged particles. These developments are not merely important but have also opened up a new field in the investigation of the propagation of chemical change through gaseous media under the most intensive conditions of temperature and pressure.

Recent Acquisitions at the British Museum (Natural History)

THE Rev. A. H. Cooke has given the whole of his collection of shells of land-snails of the genus *Clausilia* and of the dog whelk (*Thais lapillus*); the former is very rich in series from central Europe and the Balkans, and the latter includes specimens from practically the whole distributional area, and illustrates very completely the remarkable variation of this species. Recent accessions to the Department of Entomology include the final instalment, consisting of several hundred Hymenoptera, of the very large amount of material collected by the Percy Sladen Trust Expedition to the Seychelles and other islands of the western Indian Ocean. This expedition, which was led by Prof. (then Mr.) Stanley Gardiner, in 1905 and 1908–9, resulted in the gift of many thousands of specimens to the Museum. The final instalment consists almost entirely of small or minute wasps, many of them obviously new, which it has so far proved impossible to work out owing to the lack of specialists in these groups. The Department has also received a set of the Hymenoptera collected on the island of Rodriguez by the late H. J. Snell and by Mr. H. P. Thomasset. From Mount Kina Balu in North Borneo a series of a new species of *Blepharocera* has been sent by Mr. H. M. Pendlebury. Flies of this genus have hitherto been found only in the north temperate regions, and their discovery in Borneo is therefore both surprising and of importance in zoogeography. The larvæ of these insects live only in waterfalls and rapids, attaching themselves to rocks and stones by means of ventral suckers; and it has been considered therefore that they would be able to spread only along land routes. The four, widely separated, compound eyes in this species give the head a most remarkable appearance. The American Museum of Natural History has presented to the Department of Geology a model of an extinct straight-tusked elephant.

Game Animals in the British Museum (Natural History)

THE Trustees of the British Museum announce the closing of the exhibition of the game animals of the British Empire in the New Whale Gallery at the Natural History Museum on March 19. As, owing to the financial stringency, it was impracticable to begin last year the removal of the exhibited specimens of whales to their new quarters, the Trustees decided to use the space available for the temporary exhibition of the game animals, grouped by the three great faunal regions in which they occur and arranged without glazed cases. Unhappily the skins are attractive to moths; it would therefore be risky to leave the specimens exposed when the moths begin to fly in spite of the daily dusting which these skins receive, and they will be returned to their cases before the end of the month. Capt. Guy Dollman, who was responsible for the arrangement of the exhibition, will talk in the New Whale Gallery about the animals in the three great faunal regions at 11.30 on March 4, Indo-Malaya; March 11, Africa; March 18, Canada and Newfoundland. Visitors will be admitted free.

Ross Institute for Tropical Diseases

AT a recent meeting of the Industrial Advisory Committee of the Ross Institute, Putney Heath, London, S.W., reports were received of the over-seas activities of the Institute. Seven research centres in Assam and northern Bengal have been opened, and anti-malarial work and the testing of new drugs for the treatment of malaria have been pursued there and in Rhodesia and East and South Africa. In the Assam tea gardens, anti-malarial work has resulted in much improved health, for in 1930 among a population of 13,248 the admissions to hospital were 23,226 but in 1932 with a slightly larger population the admissions were reduced to 15,141. A standard oil mixture for killing mosquito larvæ has been devised in conjunction with the Burma-Shell group. The health among lead miners in Yugoslavia was investigated and a health scheme was formulated and is now in operation. At the conclusion of the proceedings, Mr. Still and Sir Malcolm Watson addressed the meeting on the subject of yellow fever. Now that travel by aeroplane is so rapid, the grave danger that infection may be carried from the yellow fever zone in West Africa to East Africa and Asia, which would be followed with disastrous consequences, was emphasised.

Norwegian Antarctic Expedition

CAPT. H. RIISER-LARSEN, the leader of the forthcoming Norwegian expedition to the antarctic, has outlined his plans in the *Polar Record* for January. With two companions and eighty dogs, he hopes to be landed from a whaler at Enderby Land early this year. A hut will be built as a base for the winter months but various sledge journeys will be made in April and May. In the spring the three men will start sledging westward over the sea-ice along the coast of the Weddell Sea to Snow Hill or Hope Bay in Graham Land, where supplies were to be landed by a whaler this (southern) summer. The expedition is to be picked up early in 1934. A short wave radio equipment will be carried which will make it possible for arrangements with the whaler to be altered. Capt. Riiser-Larsen believes, from his view of the ice during flights in recent years, that the land-ice round this coast is heavily crevassed and would make travelling difficult. On the other hand, he thinks that the sea-ice will give a suitable surface and that lines of stranded bergs prevent it breaking up near the coast. The experience of others in the Weddell Sea suggests that these are optimistic views, but Capt. Riiser-Larsen admits that if the route proves impracticable, journeys will be made in an easterly direction from Enderby Land, where there is much work to be done. The use of a sea-ice route will certainly allow plenty of seal-meat to be got for men and dogs, and so obviate the necessity of carrying full rations.

Institution of Mechanical Engineers

At the annual general meeting of the Institution of Mechanical Engineers on February 17, Mr. A. E. L. Chorlton, M.P., was inducted as president and the annual report for 1932 was adopted. The total membership of the Institution is now 11,295, a net increase for the year of 134. While the numbers of associate members and graduates show considerable increases, there has been a decrease in the numbers of members and of students. During the year Sir Alfred Ewing, Sir Henry Fowler, Sir Vincent Raven, Sir J. J. Thomson and the late Mr. W. H. Patchell were elected honorary life members. The total revenue for the year was £34,052. The report refers to the work of the various research committees and also to the educational work done. Examinations for National Certificates and Diplomas in Mechanical Engineering were held in conjunction with the education departments in England, Scotland and Northern Ireland at which 2,829 candidates sat. Twenty National Diplomas (Air) in Mechanical Engineering were awarded jointly with the Board of Education and the Air Ministry to officers of the Royal Air Force on completion of the engineering course at Henlow. In addition to the meetings held at the headquarters of the Institution, full programmes were carried out by the nine provincial branches, the average attendance of members and visitors at each meeting being more than a hundred. The gifts to the Institution include a plaque modelled by F. J. Halnon and cast in steel, showing Faraday in his laboratory, the donor being Sir Robert Hadfield.

Illuminated Fountains

Recent installations of illuminated fountains in Paris and Stockholm prove that magnificent effects can be produced in this way which fit in well with festive occasions. In the *Escher-Wyss News* for October an interesting technical description is given of an illuminated fountain which was constructed in the lake of Zurich for a 'lighting week'. A pontoon was moored 85 metres distant from the shore and away from the route of the steamers. The caisson is circular in shape, its weight is 12 tons and the upper platform is ten metres in diameter. Five pump sets are arranged in the bottom of the caisson each capable of delivering 220 lb. of water per second when the motors rotate at 1,450 r.p.m., producing a total pressure head of 20 metres. They can be connected in series or parallel. The play of the water is arranged in eight different ways producing the appearance of circles, tulips, baskets, etc. With one arrangement the main water jet rises to a height of 45 metres, the whole fountain being apparently enveloped in foam. The whole of the playing waters are illuminated by thirty-two search-lights, each taking between 1,000 and 1,500 watts. The lamps are hermetically sealed in concrete casings. The entire pontoon is painted in a neutral colour so as not to form a contrast and interfere with the picture presented by the lake. The general effect of this fountain fits in very well with the shore illuminations. The work was completed in a few weeks and the fountain was set in operation on October 1, 1932.

Steam, Electric and Diesel-Electric Traction

In a paper read before the Institution of Civil Engineers on February 21, H. W. H. Richards, electrical engineer to the London and North Eastern Railway, makes a definite comparison, both technical and financial, between steam, electric and Diesel-electric traction. The comparison is based on the existing traffic conditions of load and speed, so that it is on exactly the same basis in each case. It can be shown that the most satisfactory unit to adopt is the trailing ton-mile per annum per single track. The average traffic density for steam trains is about three million ton-miles and for electric trains which are practically confined to suburban service it is about 4·5 million ton-miles. It appears that on an average load of about fifty per cent for the complete electrification of the main lines in Great Britain, the total power of the steam turbines required for the electric service would be 3·5 million brake horse power. If Diesel-electric service were adopted throughout, the total Diesel engine power required would be 15 million brake horse power. On the same basis, the total weight of electric tractors would amount to 850 thousand tons as compared with 1,300 thousand tons for Diesel-electric tractors. The capital costs for traffic densities ranging from 2 million to 10 million ton-miles are in all cases cheapest for steam and the costs of electric and Diesel-electric services are much the same at a traffic density of 4 million, after which electric traction becomes progressively cheaper. As regards operating costs, for main line services, including interest on capital, the cost of electric traction is lower than that of steam or Diesel-electric traction at traffic densities greater than 2·5 million ton-miles.

Reading under Vibratory Conditions

In the paper on recent developments on electric lighting read by Mr. W. J. Jones to the Royal Society of Arts on November 30 and published in the Society's journal (*J. Roy. Soc. Arts*, vol. 81, p. 132) some novel experiments and phenomena were described in connexion with illumination. He showed a swinging pendulum with the letter *E* printed at various points down its shaft. The speed of translation of any particular *E* is directly proportional to its distance from the point of suspension. When the illumination on the pendulum was only two foot candles, the letter *E* could only be seen about a quarter of the way down the pendulum. But when the illumination was increased to 100 foot candles the letter *E* could be seen almost at the bottom of the pendulum. A connexion can thus be obtained between the speed of vision and illumination. Experiments were described on the effect produced by the vibration of public vehicles. When the vehicle was moving, an appreciable reduction both in the speed of reading and in visual acuity took place. Experiments made a few years ago by reading a newspaper in a train on the Bakerloo Railway when it was at rest and when it was running showed that in the former case the speed of reading was 220 words a minute and in the latter 140 words a minute. In this case the illumination was two foot candles. Tests carried out in trains and buses under similar conditions about the same time gave similar results, showing that there was an appreciable reduction in the speed of reading when the vehicle is in motion. Reading under vibratory conditions in a poor light is known to cause visual fatigue and is apt to produce headaches. We are glad to hear that in some of the London Underground railway coaches to-day, the illumination at reading level has been raised to about twenty foot candles. This automatically does much to mitigate the effects of vibration, so far as visual performance and comfort are concerned.

English Folk Dance and Song Society

THE recent amalgamation of the Folk Song Society with the English Folk Dance Society has been marked by the appearance of a new journal with the title *Journal of the English Folk Dance and Song Society*, under the editorship of Mr. Frank Howes. The contents of the first number are indicative of the policy which it is now considered desirable for the reorganised societies to pursue in common. The primary object which the original societies had in view was the collection and preservation of the remains of traditional songs and dances. This work now being regarded as completed, so far as can be seen, the main work of the joint society on its scientific side will be intensive comparative study of the material which has been collected. In the first issue both activities, it is true, are represented. Ten more of the forty Gaelic songs collected by Miss Lucy Broadwood twenty-five years ago are published, as well as some English folk songs and dances recently recorded. On the comparative side, Mr. A. G. Gilchrist makes an exhaustive study of the Scottish and Northumbrian ballad Lambkin, discussing its growth and origin in the light of some forty versions. Similar studies of no little interest to students of culture and of 'survivals' and their distribution are Miss Violet Alford's record of the form and distribution of the Farandole in the south of France and in Spain and the study of the sword-dance by Dr. R. Wolfram of Vienna, who connects it with the initiation ceremony, seeing in the decapitation of the 'fool' the ritual death of initiation rather than the memory of a fertility sacrifice.

Sadi Carnot, 1796–1832

IN *La Nature* of February 1, under the title "Grandeur et Modestie d'un savant Français: Sadi Carnot", M. Roger Vène gives a sketch of the life and character of the young French engineer who wrote the famous essay "Réflexions sur la puissance motrice du feu". Carnot was only twenty-eight years of age when he published the essay, and he died of cholera eight years later. According to the regulations, the clothes and papers belonging to the victims of the cholera epidemic which swept through Paris in 1832 were to be destroyed, but fortunately some of Carnot's manuscripts were saved by his friend Clapeyron. Born in the Petit Luxembourg when his father, Lazare Carnot, was a member of the Directory, Sadi had a brilliant career as a student of the Ecole Polytechnique but was too young to take part in the Napoleonic Wars, and his life was spent mainly in the routine of the barracks. The extracts given by M. Vène reveal a charming personality. The article is accompanied by a portrait of Carnot at the age of seventeen years. An article on Carnot appeared in our columns on August 20, 1932 (p. 266).

Plant Pathology at Rothamsted Experimental Station

THE Committee of Management of the Rothamsted Experimental Station recently decided to reorganise the old Department of Mycology, started in 1918 under the charge of Dr. W. B. Brierley, now professor of agricultural botany at the University of Reading, and to constitute it a Department of Plant Pathology with Dr. J. Henderson Smith as head. Dr. Henderson Smith studied medicine at Balliol College, Oxford, and then proceeded to the University of Edinburgh, where he took his medical degree; he was then awarded the Philip Walker studentship in pathology, which he held at Oxford until his appointment first as bacteriologist at the Lister Institute and afterwards as plant pathologist in the Mycology Department at Rothamsted. He has published numerous papers on animal pathology, especially immunity and bacteriology, and on plant pathology, especially virus diseases.

Motor-Car Speed Record

ON February 22, Sir Malcolm Campbell broke his own motor-car speed record on Daytona Beach, Florida, in his car the *Blue Bird*. On the southward run Sir Malcolm covered the mile in 13·16 sec. and in the northern run in 13·60 sec. His mean speed worked out at 272·108 miles per hour, thus being well ahead of his record of 253·978 miles per hour set up last year. The *Blue Bird* is fitted with a Rolls-Royce engine developing 2,350 H.P. at 3,200 R.M.P. The engine has a bore of 6 in. and a stroke of 6·6 in. This type of engine was also installed in the aeroplane which won the Schneider Trophy for Great Britain and in the machine in which Flight-Lieut. Stainforth achieved the world's present air speed record of 407·5 miles per hour.

British Fresh-Water Fishes

THE Trustees of the British Museum have published a second edition of their "Guide to the British

Fresh-Water Fishes" exhibited in the Department of Zoology of the British Museum (Natural History). This edition has been revised by the original author, Dr. C. Tate Regan; it is practically a reprint of the 1917 edition with one or two very minor alterations, but the paragraph on the common eel has been rewritten to include the new knowledge gained in recent years on the life-history of this fish through the researches of the late Dr. Johannes Schmidt. This publication, which is still priced at sixpence, is an invaluable little handbook for the identification of the fresh-water fishes of Great Britain.

Amphibia and Reptiles of North China

A CONCISE and excellent "Handbook of North China Amphibia and Reptiles" by Dr. Alice M. Boring, C. C. Liu, and S. C. Chou, has been published as a Peking Natural History Bulletin (August 1932). It contains keys for the identification of the various families, and of eggs and tadpoles of the species of frogs and toads. The descriptions of the characteristic structures and habits of species, and the excellent drawings, should greatly help the natural history survey of the country, which is one of the objects of the Peking Natural History Society.

Mr. T. Sheppard and the *Naturalist*

WITH the close of 1932, Mr. T. Sheppard retired from the editorship of the *Naturalist*, having served it as editor for thirty years. As an illustrated monthly journal, designed for readers within the domain of the Yorkshire Naturalists' Union, the *Naturalist* has maintained a high standard, and in its comments and reviews it conveyed a touch of the editor's vitality and boisterousness. The occasion of his retirement was made an opportunity of presenting Mr. Sheppard with his portrait in oils by Mr. Vincent Galloway.

Kansu Earthquake of December 26

EARLIER than was expected, reports have arrived from north-west China about the earthquake of December 26 (local time). From these, it appears that 280 persons were killed and 300 seriously injured, while 800 houses were destroyed. These losses occurred in the north-west of Kansu, one of the Chinese provinces most frequently visited by disastrous earthquakes.

Announcements

DR. F. A. BATHER has been awarded the Mary Clark Thompson medal of the National Academy of Sciences, Washington, "for his distinguished services in the fields of palæontology and geology".

THE tenth annual conference of the Association of Special Libraries and Information Bureaux will be held at the Wills Hall, Bristol, on September 22-24, under the presidency of Sir Charles Sherrington. Further particulars can be obtained from the Secretary of the Association, 16, Russell Square, London, W.C.1.

AT the annual general meeting of the Association of Economic Biologists held in the Imperial College of Science, London, on February 24, the following officers for the ensuing year were elected:—*President*, Prof. W. B. Brierley; *Vice-Presidents*, Prof. J. W. Munro, Prof. W. Brown; *Hon. Treasurer*, Dr. J. Henderson Smith; *Hon. Editors*, Prof. W. B. Brierley, Prof. J. W. Munro; *Hon. Secretaries*, Prof. R. H. Stoughton, Mr. G. Fox-Wilson.

AT the ninety-first meeting of the American Association for the Advancement of Science, which was held on December 27-31, at Atlantic City, Prof. Henry Norris Russell, research professor in astronomy and director of the Observatory at Princeton University, was elected president for the ensuing year, and Prof. Henry B. Ward, who retires from the professorship of zoology in the University of Illinois in June next, was elected permanent secretary. The American Association prize of 1,000 dollars has been awarded to Dr. Henry Eyring, of Princeton University, for a paper entitled "Quantum Mechanics and Chemistry, with particular Reference to Reactions involving Conjugate Double Bonds".

THE Oxford University Press will publish in April the first number of a new *Empire Journal of Experimental Agriculture*. This journal will offer agricultural research workers in the British Empire a medium for disseminating the records and results of their investigations on the feeding and management of livestock, cultivation and manuring of crops, trials of farm machinery, agricultural economics and experimental technique. The *Journal* will command a strong editorial Board, including, among others, Sir John Russell, Sir Rowland Biffen, Sir Daniel Hall, Sir Robert Greig, Sir Frederick Keeble and leading agricultural authorities in the chief countries of the Empire. Dr. E. H. Tripp, 40 Trewsbury Road, Sydenham, London, S.E.26, is secretary and general editor. The *Journal* will be published quarterly: subscription price 20*s.* for four numbers or single numbers 7*s.* 6*d.* net, each.

APPLICATIONS are invited for the following appointments, on, or before, the dates mentioned:—A mathematics master at the Junior Technical School of the Wimbledon Technical College—The Principal (March 10). An assistant lecturer in zoology at the University of Manchester—The Registrar (March 11). A teacher in electrical engineering subjects at the Southall Technical College—H. M. Walton, Education Offices (H), 10, Great George Street, London, S.W.1 (March 21). A woman tutor in hygiene and biology at the Edge Hill Training College, Ormskirk, Liverpool—The Principal (March 24). A director of the Royal Technical College, Glasgow, and a professor of technical chemistry at the College—The Secretary (April 17). Physicists and electrical engineers for the staff of the Radio Research Board of the Commonwealth of Australia Council for Scientific Research—F. L. McDougall, Australia House, Strand, W.C.2.

ERRATUM.—NATURE, February 25, p. 268, col. 2, paragraph entitled "Fat in Æstivating Animals", line 13 for *Pachyurus* read *Pachyuromys*.

Supplement to NATURE

No. 3305 MARCH 4, 1933

Reviews

Pliny's Chemical Knowledge

The Elder Pliny's Chapters on Chemical Subjects. Part 2. Edited, with Translation and Notes, by Dr. Kenneth C. Bailey. Pp. 299. (London: Edward Arnold and Co., 1932.) 15*s.* net.

"IT occurs to one to marvel at the persistent experimenting of humanity," said Pliny, "which has exempted neither dregs nor foulest residues from the most varied examination." It did not occur to him—vain though he was—to marvel equally at his own persistent accumulation of the most varied scraps and orts of knowledge. What a contributor, through accident of time, was lost to "Notes and Queries"! So vast is the extent of the "Natural History" that few men, in these rapid days, can have read the whole work; and so heterogeneous is it that probably few men would care to do so. Yet to the historian of chemistry, Pliny must be of paramount importance as a source-book of Roman chemical knowledge, not only because his mass of information is so great, but also because there are so few other sources of any kind. It is therefore with peculiar pleasure and satisfaction that we welcome the second and concluding part of Dr. Kenneth Bailey's book, in which all the important chemical passages not contained in the first part are collected, translated, and very adequately annotated.

Among the interesting facts that Pliny describes is the manufacture of cadmia or zinc oxide by roasting zinc ores. "It is made", he says, "when the most subtle portion of the charge is expelled by the fiery blast and deposited either in the roof-chambers or on the furnace-walls, in accordance with its density." As in modern practice, the product was graded by density and the distance to which the fumes were carried, the best quality occurring inside the furnace itself, where it hung from the arches of the roof-chamber. Ores containing zinc were well known to the Romans, and it appears probable that the alloy which we call brass was indeed a Roman discovery. Dr. Bailey observes that Roman copper coins from Augustus to Gallienus regularly contained zinc, and that brasses discovered at Silchester are practically identical in composition with Tournay's alloy (copper, 82·5; zinc, 17·5), used extensively for the imitation of gold.

Upon lead, Pliny remarks that it "is mined with great toil in Spain and in all the divisions of Gaul, but occurs in Britain in the surface stratum of the ground, and in such abundance that the amount refined is actually limited by law". It is a little surprising that in his note on this passage, Dr. Bailey, though mentioning the occurrence of lead in Cornwall, Derbyshire, Cumberland and Shropshire, does not refer to the extensive Roman lead mines on the Mendips—those *montes minerarii, plumbi admodum fertiles*—where the largest pig of Roman lead ever found in Britain was discovered at Charterhouse-on-Mendip in September 1873. Possibly his attention was momentarily distracted by the delightful application of lead described a few lines further on: "Nero, by the will of the gods Emperor, used to sing solos with a sheet of lead over his chest, and thus demonstrated a method for maintaining the voice"!

Verdigris, used in salves and for other medicinal purposes, was manufactured in various ways, such as sprinkling vinegar on copper filings and stirring the mixture several times a day with a spatula until the reaction was complete. The product, especially that exported from Rhodes, was frequently adulterated with powdered marble, pumice or gum, but more particularly with shoemakers' black (ferrous sulphate). Pliny says, quite rightly, that the presence of the last adulterant may be detected by means of a piece of paper steeped in extract of gall-nuts, which is immediately blackened by verdigris containing *atramentum sutorium*. Such versatility in experiment as is implied by qualitative tests of this recondite nature renders all the more incomprehensible the later fortunes of chemistry, with its 'artificial' gold and silver almost universally accepted as genuine.

Among the properties of blue or green vitriol Pliny mentions its use to cure deafness, to expel intestinal parasites, to relieve pains in the eyes, and to cleanse ulcerous excrescences. But it is plain that he likes best of all the "recent discovery for use in the arena", namely, that if vitriol is thrown into the faces of bears or lions, it exercises so powerful an astringent effect as to prevent them from biting.

The prevention of the rusting of iron, though not so urgent a problem for the Romans as for the modern world, had received attention. Pliny complacently remarks that, as iron inflicts most loss on short-lived humanity, a benevolent nature showed laudable foresight in exacting from it the penalty that it needs must rust; but he goes on to say that it may be protected against rust by white lead, gypsum, or pitch. He also relates the story (without lending it his support) that rusting may be prevented by a suitable religious ceremony, and mentions that an iron chain was still in existence, at Zeugma on the Euphrates, which was used by Alexander the Great in bridging the river there. "Those links which have been renewed are a prey to rust, from which the original links are quite free." The iron pillar at Delhi is an indication that the production of rustless iron is perhaps not altogether a modern achievement, and the story of Alexander's chain may possibly have some foundation in fact.

It would be easy to lengthen considerably this selection of extracts from Pliny's engaging story, for no page is without its interest and its problem. The interest is Pliny's own, who in the end discovered more about sulphur dioxide than its bleaching and germicidal powers; but the solution of most of the problems is due to Dr. Bailey, whom we may once again thank for his careful and ingenious labour. E. J. HOLMYARD.

Comenius in England

Comenius in England: the Visit of Jan Amos Komenský (Comenius), the Czech Philosopher and Educationist, to London in 1641–1642; its Bearing on the Origins of the Royal Society, on the Development of the Encyclopædia, and on Plans for the Higher Education of the Indians of New England and Virginia, as described in Contemporary Documents. Selected, translated and edited, with an Introduction, and Tables of Dates, by Robert Fitzgibbon Young. Pp. vii + 99 + 12 plates. (London: Oxford University Press, 1932.) 10*s.* net.

JAN AMOS KOMENSKÝ, the famous Czech philosopher and educationist, better known by his Latinised name, Comenius, was born at Uherský Brod, Moravia, in 1592. He spent a few years at the University of Herborn, in Germany, under Alsted, whose encyclopædic ideas he was later to develop. Comenius returned to teach for a time in Moravia, but his promising career was interrupted by the Thirty Years' War which began in 1619. As one of the Bohemian Protestants, Comenius went into exile in 1628 and settled at Leszno in Poland, where he taught at the college of the *Unitas Fratrum* and wrote some of his remarkable Latin and vernacular educational works which are still of interest to-day.

Always hoping to be allowed to return to his native land, Comenius made many journeys across Europe. Everywhere he impressed men of learning by his teaching abilities, his writings and by his pansophic plans. He conceived the idea of erecting an international college or academy of sciences where every branch of human knowledge would be studied and made available in encyclopædic form. Such a 'universal college' was to be a "living laboratory supplying sap, vitality and strength to all".

At this time great developments in mathematics, physics and biology were taking place in England and elsewhere as an aftermath of the humanistic Renaissance of the fifteenth century. Comenius's all-embracing schemes appealed to contemporary scholars and through Samuel Hartlib, a native of Elbing in East Prussia, they were made known in England.

In 1641 a group of members of both Houses of Parliament invited Comenius to England. He arrived on September 21, 1641, and remained until June, 1642. The exact influence of Comenius upon his English contemporaries is difficult to ascertain and for this purpose Mr. R. Fitzgibbon Young has collected in his valuable monograph the relevant documents (ten in all) describing Comenius's plans for a Baconian college and other details of his visit to London. From these carefully annotated documents it is clear that many influential scholars (including several who were later prominent fellows of the Royal Society) and public men were favourably impressed by these plans.

Unfortunately, more urgent matters absorbed the attention of Parliament and the plan for a universal college was abandoned. Only after the Restoration in 1660 was it possible to make use of some of Comenius's ideas when the Royal Society was incorporated in 1662. As outlined in his "Via Lucis", which was written whilst he was in England, Comenius intended his college or society to serve as a meeting-ground and intellectual clearing-house for men of science from all over the world and it is interesting to note that, from its inception, the Royal Society had a certain international character through its foreign members and correspondents.

There is no doubt that Comenius was deeply disappointed when he found that his plans could not be realised in England. His subsequent efforts in Sweden and Holland were no more successful, but he rejoiced later when the Royal Society was founded and he dedicated his "Via Lucis" to it in 1668.

Mr. Young has also discovered interesting evidence which seems to indicate that whilst in England, Comenius was approached by John Winthrop, Governor of Connecticut, with the view of visiting America and establishing a college for educating the Indians of New England, but this also did not materialise.

Mr. Young has included tables of dates of events in the life of Comenius and illustrating the development of scientific societies. He throws fresh light upon the origins of the Royal Society and the general development of plans for scientific societies and for the compilation of encyclopædias in the seventeenth century. He is the first to point out that Comenius's ideas found fruition in the writings of G. W. Liebniz, who, with Comenius's grandson, Bishop D. E. Jablonski, was the principal founder of the Berlin Academy of Sciences in 1700. J. G. F. D.

Sir Bertram Windle

Sir Bertram Windle, Bertram Coghill Alan Windle, F.R.S., F.S.A., K.S.G., M.D., M.A., LL.D., Ph.D., Sc.D.: a Memoir. By Dr. Monica Taylor. Pp. xiii + 428 + 4 plates. (London: Longmans, Green and Co., Ltd., 1932.) 12*s.* 6*d.* net.

BY a stroke of good fortune it has been possible to secure for the writing of this memoir the services of one who—a distinguished pupil of Prof. Graham Kerr—shared both the scientific interests and spiritual emotions of her subject. Those who knew how deep his religious sense, how strong his liturgical leaning, will appreciate how incomplete would be any memoir of Windle in which this side of his personality was not adequately represented. Another cause for congratulation is that not merely has the task been entrusted to sympathetic hands, to the hands of one who shared his technical knowledge of that branch of biology, cytology, which particularly interested him, but also to the hands of one who obviously possesses rare literary ability, the result being that we are given a complete, intimate and vivid portrait of a very remarkable man.

No one who ever entered Windle's presence could fail to realise that he was an outstanding personality, an impression which, if we can analyse such things, was largely due to the sense of energy and power which he conveyed: the charm of his personality, great and irresistible, was only clearly disclosed to his friends and only fully to them in his rare moments of ease and relaxation.

His life naturally falls into three periods, spent in centres so apart as Birmingham, Cork and Toronto. It was in Birmingham that his scientific investigations began and ended, for already before he left that city his energies were being more and more employed in general educational work—the foundation of the University (the first civic university in England), the organisation of its faculty of medicine, the chairmanship of the Education Committee of the General Medical Council, the performance of almost innumerable offices in connexion with general education in the Midlands. Had he continued his scientific investigations, they would in all probability have been along the lines of experimental embryology, a subject of unfailing interest to him and one to which he had been led by his studies in teratology —for many years he contributed an annual summary of the literature on this subject to the *Journal of Anatomy*—and in cytology, studies which made him an early member of the vitalistic school.

In Cork, where he went as president of Queen's College, Windle found ample scope for his energy and ability in the re-organisation of the College—adding to its buildings, dividing up its departments, enlarging its staff, improving residential accommodation for its students and taking an active general interest in the welfare of its staff and students. He was particularly successful in securing increased grants and generous benefactions, with the result that the College rapidly rose in status. Although he never achieved his ambition of converting the College into a university—the University of Munster—he was largely instrumental in its becoming one of the three university colleges in the National University of Ireland. As in Birmingham, his interest in education was far from being confined to the institution with which he was officially connected. He became a well-recognised figure on the platform, often in the chair at meetings throughout the country and was one of those nominated by the Prime Minister as a member of the Irish Convention of 1917.

At the close of the War, the dismal rôle for which Ireland above all countries seems to be cast, that of 'stoning the prophets', in other words, driving into exile those most willing and best fitted to serve her, came again to be played. The strange and violent opposition of Sinn Fein to Windle's project of a university for Munster, the project which had been close to his heart ever since his first landing in the country and to which the major part of his energies had been persistently bent, made his resignation inevitable and irrevocable.

The last period of Windle's eventful history was spent in Toronto where, far now from Ephesus, he spent the evening of his life in the quiet air of congenial studies, writing and lecturing on many subjects, some as diverse as Roman Britain, Thomas Hardy, science and religion. As always, he played an important part in the life of the city, being particularly prominent in connexion with university institutions and medical charities.

Such in barest outline is the record of a life and career of ceaseless activity and high distinction, a record which Dr. Taylor, assisted by an unusually large number of intimate letters, but yet with consummate knowledge and skill, has been able to convert into a narrative of absorbing interest, placing incidentally the many friends of Windle under a debt of deepest gratitude.

William Wright.

Georgia and its People

A History of the Georgian People: from the Beginning down to the Russian Conquest in the Nineteenth Century. By W. E. D. Allen. Pp. xxiv+429+31 plates. (London: Kegan Paul and Co., Ltd., 1932.) 31*s*. 6*d*. net.

IN a laudatory introduction to this book, Sir Denison Ross emphasises the scant attention Georgia has received latterly from historians and other scholars. Since the publication of Brosset's "L'Histoire de la Géorgie", three quarters of a century ago, nearly everything that has been written relating to the people and the country has appeared in either Russian or Georgian. For this, no doubt, its troubled history in the earlier half of the last century is responsible; but it is surprising that a country, of which the beauty and charm has been celebrated by more than one Russian writer well known to the western world, should have been thus neglected in later years.

Mr. Allen's "History of the Georgian People" covers a long range of time. He begins with the bronze age and ends with the beginning of the nineteenth century, when the Georgian kingdom fell before Russia, although the country was not completely subdued until many years later. Mr. Allen does not write as an archæological expert. His account of the prehistoric period is a summary of the views generally accepted by archæologists at the moment, but it is none the less to be appreciated on that account. He marks how little is known with certainty and how great a field for exploration is offered in this little-known area, which not only includes the ancient Colchis, but was also evidently in more or less close touch with the Hittites and, probably, with other early empires of the Middle East. The archæology and ethnology of a people speaking a language with no proved affinities clamour for intensive study.

An enormous mass of information in Russian and Georgian, mostly from the periodical literature of learned societies, has been digested in the preparation of this history. The story of the medieval Georgian kingdoms is virtually a new chapter in history, which in its account of the relations of the Georgian monarchs to Mongol, Turk and Persian is of interest not merely as it affects the Caucasus, but also for the sidelights it throws on the history of the various peoples and rulers with whom the Georgians were in contact. It is instructive, for example, to see how the tolerant rule of the early Mongol conquerors actually functioned from the point of view of the conquered country.

In addition to the historical sequence of events, Mr. Allen deals with the development of the social and economic organisation of medieval Georgia and its religion, literature and art. Each of the chapters on these subjects is valuable, but the account of the social organisation, tracing its growth from the primitive congeries of family groups at about the beginning of the Christian era to the feudalised kingdom, is a field untouched by, and indeed unknown to, European sociologists. The picture of manners and customs places in a true perspective the somewhat coloured accounts of de Chardin, Tournefort and other travellers of the late sixteenth and early seventeenth centuries.

Mr. Allen has added considerably to the interest of his narrative by his illustrations, some of which show striking examples of Georgian art, while others are portraits and sketches which illustrate arms and dress at different periods from contemporary Georgian sources.

British County Flora

The Comital Flora of the British Isles (Flora Comitalis Britannicæ: Fl. Com. Brit.): being the Distribution of British (including a number of Non-Indigenous) Plants throughout the 152 Vice-Counties of Great Britain, Ireland and the Channel Islands, with the Place of Growth, Elevation, World-Distribution, Grade, Chief Synonyms and First Names by which the Plants were recorded as British. By Dr. George Claridge Druce. With an original coloured Map showing the Botanical Vice-Counties presented by William James Patey. Pp. xxxii + 407. (Arbroath: T. Buncle and Co., 1932.) 20*s*.

In his introduction, Dr. Druce gives an account of the work of Hewett Cottrell Watson, who devoted many years of a long life to the study of the geographical distribution of our British plants. Watson divided the country into provinces, sub-provinces and counties or vice-counties (112 in number) and also employed terms to indicate altitudinal distribution and the nature of the habitat. His results were collected in two classic works, the "Cybele Britannica" in four volumes (1847-59) with a "Supplement" (1860) and the "Topographical Botany" in two parts (1873-74). A second edition of the last-named was prepared by J. G. Baker and the Rev. W. W. Newbould and two "Supplements" have since been published in the *Journal of Botany*, the first by Arthur Bennett (1905), the second by Bennett, C. E. Salmon and J. R. Matthews (1929-30). Dr. R. L. Praeger's "Irish Topographical Botany" (1901), with "Supplements" in 1906 and 1929, is authoritative for the Irish counties.

These works together with "Floras of the Channel Islands" by Lester-Garland and Marquand form the basis of the "Comital Flora" in which Dr. Druce essayed to collect in one volume all available information. The plan of the work is as follows: the scientific and popular names of the plant are followed by its more important synonyms; the natural habitat, altitudinal and horizontal distribution according to Watson's vice-counties, are given, and finally the first record of the species as British based mainly on W. A. Clarke's "First Records of British Flowering Plants".

The volume, appearing so shortly after the author's death, is a memorial of his industry and his devotion to the study of our British flora; and is valuable as bringing together much scattered information. Its defects are traceable to the personality of the author, and perhaps also to hasty production, excusable in a man who has completed his four-score years. Dr. Druce was unwilling to merge his own opinions in the compromise involved in the acceptance of generally agreed rules of nomenclature, and the student will find in the pages of the "Flora" familiar plants under unfamiliar names, such as *Dondia* for *Suæda*, *Juncoides* for *Luzula*, and *Savastana* for *Hierochloe*; and whereas botanists in council have 'barred' tautonyms, Dr. Druce uses such combinations as *Meum Meum* Druce. A more serious fault is the failure to deal more fully with large and critical genera where the information was ready to hand—as in the case of *Rubus* in the work of Moyle Rogers and of more recent botanists, and *Euphrasia*, the British species of which have been treated in detail by Rigsley. The notes on the general geographical distribution of the species are sometimes incomplete—*Najas flexilis*, for example, is cited as European but occurs also in North America—or even inaccurate; and errors in the records of vice-county distribution are noticeable.

The book is neatly bound and of convenient size for a hand-book; the typography is well arranged and clear; and a large, coloured map indicating the vice-counties in Great Britain and Ireland, included as a folder, is a useful addition.

Experiments on Memory

Remembering: a Study in Experimental and Social Psychology. By Prof. F. C. Bartlett. (The Cambridge Psychological Library.) Pp. x + 317 + 3 plates. (Cambridge: At the University Press, 1932.) 16*s*. net.

PROF. BARTLETT'S experimental investigation of remembering is to be welcomed as a valuable scientific investigation which, in many ways, breaks new ground. During the years since Ebbinghaus invented the experimental method which makes use of nonsense syllables, it is probable that as much has been discovered by this method as ever will be. On the whole, the results have been disappointing.

With the passing of interest in the laws of association, which are now recognised to be merely the laws of thought habit formation and not the fundamental laws of effective thinking, new ways of study have become necessary. Prof. Bartlett has used a method in which folk-lore stories, news stories, drawings, or other items of meaningful material are successively reproduced by a single person or are handed on from person to person. Particularly interesting are the results of the latter kind of experiment, which demonstrate the process of social conventionalisation by which folk stories may be supposed to have been formed and by which originally representational drawings may have been conventionalised into the letters of the alphabet.

The present stage of development of experimental psychology is undoubtedly one in which the widest possible variety of methods is to be encouraged since no one knows which will be most fruitful. It is a pity that Prof. Bartlett allows himself to attack the use of statistical methods, which provide one of the most promising methods of approach. He complains that statistical methods are scientific makeshifts because they are only used on data in which disturbing causes prevent the appearance of invariable relationships. This, however, is really an argument for excluding all quantitative problems in which relationships are not invariable (that is, those in which there is merely a 'tendency' for an effect to appear in certain conditions) and is not an argument for admitting tendencies to relationship without adequate consideration of the problems of chances of sampling. Prof. Bartlett himself refers to many tendencies which arise out of his work. Thus, on p. 61 it is stated that visualisation 'tends' to lead to confusion as to order of presentation and 'favours' the introduction of extraneous material, while vocalisation 'favours' a certain kind of classification and 'tends' to set up an attitude of uncertainty.

Prof. Bartlett is a careful and self-critical investigator and it is most likely that he has adequate evidence for these tendencies, but he does not give the figures which alone can enable us to determine the likelihood that these are not spurious tendencies produced by the chances of sampling. The truth is that in many biological inquiries, and particularly in psychological ones, the choice is not between invariable relationships and tendencies. The most carefully controlled conditions will not make the observed relationships invariable. The choice is between inadequate treatment of observed tendencies and their adequate treatment by the use of statistical methods.

Prof. Bartlett's theoretical chapters on the theory of remembering, on the functions of images and on meaning are a valuable contribution to the subject. He rejects the over-simple 'memory-trace' hypothesis, still too popular amongst the teachers of allied sciences, and bases his own view on Head's theory of 'schemata'. He describes remembering as "an imaginative reconstruction, or construction, built out of the relation of our attitude towards a whole active mass of organised past reactions or experience, and to a little outstanding detail which commonly appears in image or in language form" (p. 213). R. H. T.

The Process of Metamorphism in Rocks

Metamorphism: a Study of the Transformations of Rock-Masses. By Dr. Alfred Harker. Pp. x + 360. (London: Methuen and Co., Ltd., 1932.) 17*s.* 6*d.* net.

A RICH store of observations especially on the metamorphic rocks of Great Britain, numerous excellent drawings of rock sections as seen in the microscope and admirable clarity of statement are the outstanding features of this new book on metamorphism. In the first part, which is devoted to thermal metamorphism, general genetic considerations occupy about one-third of the space and are followed by a detailed account of the thermal metamorphism of argillaceous, calcareous and siliceous sediments and of igneous rocks. Especially in connexion with the last named, much interesting information is given. The second part treats in similar fashion of dynamic and regional metamorphism with very brief chapters devoted to injection, repeated and retrograde metamorphism.

Throughout the book the reader is left with the impression that the author's knowledge of metamorphism is based on the rocks of Great Britain and is struck by the fact that a discussion of the conditions prevailing in the oldest formations as in the youngest, for example, the fold-system of the Alps, is largely wanting. In these circumstances the systematic and most important parts of the book offer an interesting counterpart to publications dealing especially with archæan and alpine metamorphism. But it is no less true that the limitations thus indicated, to which must be added the fact that a lack of references to the non-English literature of the past twenty years is very noticeable, constitute a real shortcoming in the work as a whole. It is greatly to be feared that this book with all its obvious advantages (should it come to be used in Great Britain as a compendium of contemporary knowledge on metamorphism) will tend by what it omits to delay the adaptation of many results of modern research to the further study of British metamorphics. A divergence between the Continental and British schools of metamorphism might thus arise, which could only be of mutual disadvantage.

Dr. Harker stresses the point that his text is equally allotted between thermal and dynamic metamorphism and that he is more concerned with the processes than with the results of metamorphism. In these respects he believes his point of view to be in contrast to that of what he calls the "German School" but which more correctly should be termed the Austrio-Swiss or Alpine School after its most eminent representatives, F. Becke and U. Grubenmann. This assumption, which is the starting point of the book, is in two respects erroneous. For, on one hand, it has apparently escaped the author's notice that a third edition of Part I of Grubenmann's book "Die kristallinen Schiefer" appeared in 1924 under the title "Die Gesteinsmetamorphose" and treats practically only of the processes of metamorphism. Thermal and dynamic metamorphism are discussed separately and full account is taken of the general physico-chemical principles governing these processes. If, secondly, Grubenmann in his systematic part was mainly concerned with the products of metamorphism, it must not be taken to mean that he (or Becke) was indifferent to the processes as such. It was, however, necessary to clear up the question of terminology, to bring out the importance of the chemical composition of the original rocks and to find a basis on which to discuss polymetamorphic rocks or such, about the mode of metamorphism of which nothing precise is known. Dr. Harker has, of course, to deal with all these questions, too, but no progress is achieved when vague terms such as "argillaceous sediments", "basic igneous rocks", etc., are used instead of the preciser information given by the chemical classification in the older book.

It must be considered a serious omission in the book that no mention is made of the question of *Gefügeregelung*, of the methods used in its investigation or of its dependence on tectonics. The names of the Austrians, Sander and Schmidt, who in the past twenty years have done work of the greatest importance and have recently published books, are not even mentioned. Very many phenomena connected with pneumatolysis, injection, assimilation and palingenesis are left untouched, so that the impression gained from Dr. Harker's treatment is quite inadequate as regards the complexity of these processes.

It is obvious that the various points mentioned in no wise lessen the value of what Dr. Harker has written, so long as the reader is aware of the limitations in the treatment. For the alpine petrographer, for example, much of the information, based as it is on accurate observation, will be of the greatest interest. At the same time, it is to be hoped that a book which may be described as the most important contemporary English work on metamorphism, will not obscure the existence of some wider issues in metamorphic petrography which are of very real importance to the subject as a whole. P. NIGGLI.

Early History of the British Coal Industry

The Rise of the British Coal Industry. By Prof. J. U. Nef. In 2 Vols. (London School of Economics and Political Science (University of London): Studies in Economic and Social History.) Vol. 1. Pp. xiv+448+14 plates. Vol. 2. Pp. vii+490. (London: George Routledge and Sons, Ltd., 1932.) 42*s*. net.

THE above work is in many respects a very remarkable one. First of all it is sufficiently curious that a professor in the heart of the United States, in Chicago, which is not even a coal-mining centre, should concern himself with a study of the coal industry of Great Britain. The material which the author has made use of is also very remarkable both for the extent of the resources of which he has availed himself and of those which he has overlooked. He himself admits in his preface that he has not made as much use as he might have done of the important work by Messrs. Ashton and Syke, "Coal Industry of the Eighteenth Century"; he appears to have entirely overlooked that valuable compilation "Historical Review of Coal Mining", published by the Mining Association of Great Britain in 1925 in connexion with the Wembley Exhibition, and he has not made any really effective use of the very valuable collection of manuscripts and other documents in the possession of the North of England Institute of Mining and Mechanical Engineers.

Had his researches been somewhat more extended, Prof. Nef would probably not have taken the same limits to his work as he has done, because he puts down the growth of the British coal industry as having taken place between the dates 1550 and 1700, basing his arguments upon the following statistics: he states that the vend from the Newcastle coalfield in 1564 was a little less than 33,000 tons, whilst in the year 1700 it was 650,000 tons, and in 1864 it was approximately 18,350,000 tons. He shows that the rate of multiplication in the first period was very much greater than in the latter periods. But surely the rate of multiplication is not the correct basis for an estimate of this kind, which should be rather the rate of addition than the rate of multiplication. It is quite true that in the year 1550 very little coal was consumed, and in the year 1700 there was a much greater consumption of coal, owing no doubt to the increasing scarcity of wood, which caused coal to come into fairly extensive use for domestic purposes. No doubt the increase in domestic consumption had something to do with the fact that at the earlier date most of the coal available would be outcrop coal, which, as is well known, is very much dirtier than coal obtained from greater depths in the seam, where surface effects have probably disappeared.

Of course, by selecting arbitrarily the year 1700 as the end of his investigation, Prof. Nef has missed entirely the great main reason for the expanse of the British coal industry, namely, the use of coal for the generation of power and for the smelting of iron, which came in, as is well known, towards the end of the eighteenth century. Furthermore, it was towards the end of the eighteenth century that the power-loom was invented, which would have been practically useless without the steam engine to drive it or iron made by the use of coal to construct the machinery. Then again, even at the beginning of the nineteenth century means of transport were exceedingly bad; the first railway (another utilisation of steam and therefore of coal) was not opened until 1822, and even at the beginning of that century roads were few and extremely bad.

It may fairly be claimed that whatever developments future ages may have in store, there will probably be none of such far-reaching importance as the application of the latent energy of coal to the generation of power. Until that date the only energy made use of by mankind had been kinetic (that is, visible) energy; even potential energy, such, for example, as that of water at a high level, was not really used until the water was in motion and made to turn a wheel, so that even in this case it may fairly be said that kinetic energy was the source of power. Possibly at some future date we shall learn to make use of atomic energy, but even such a discovery would be less epoch-making than the discovery that latent (that is, invisible) energy could be pressed into the service of mankind.

The fact that both the use of coal for the production of power and the use of coal for the production of iron were British inventions necessarily contributed enormously to the development of the British coal industry. Again, Murdoch's discovery of coal gas was not made until the very close of the eighteenth century, or a century after Prof. Nef has thought fit to close his review of the rise of British coal mining, yet to-day more than ten per cent of the coal produced in Great Britain is gasified, whilst the consumption of coal for iron-making averages something like eight per cent.

Prof. Nef seems to have overlooked the fact that for many centuries Great Britain was the world's leading producer of coal; indeed it was not until the year 1899 that the British output—obtained from this one small island—was exceeded by the output from the United States with its vast territory. In fact, the coal trade of Great Britain continued on a steady increase until well into the twentieth century; the output of British coal for 1913 (the year before the War) was not less than 287·43 millions of tons, of which more than one-third was exported. Even to-day when the output has necessarily fallen off considerably, for reasons which are perfectly well known but need not be discussed here, Great Britain is producing more than seventeen per cent of the world's coal, whilst according to the latest statistics, its coal resources are barely 2½ per cent of those of the whole world. In other words, Great Britain is producing something like seven times as much coal as its known resources should entitle it to do, and even if we admit that the zenith of the British coal industry has been passed, we are still, in comparison to our resources, by far the world's greatest coal producers.

Although, therefore, one cannot possibly agree with Prof. Nef as to the limits within which he has attempted to restrict the rise of the British coal industry, seeing that the maximum output of British coal was probably about ten times as great as it was in the year which he has selected for the close of his survey, one is bound to admire the industry which he has shown in compiling the great mass of facts, some of them by no means easy of access, which relate to the period to which he has chosen to confine his attention. We may perhaps express the hope that at some not too distant date he will complete his history up to, say, the commencement of the War, which probably marks the zenith of British coal production.

Evolution of Hydrodynamics

Hydrodynamics. By Sir Horace Lamb. Sixth edition. Pp. xv+738. (Cambridge: At the University Press, 1932.) 45*s.* net.

THE development of a book through successive editions is very like the evolution of a species. It has to adapt itself to changed circumstances by the insertion of new material; portions cease to be of explicit use, sometimes through the acquirement of new methods that do the work better, sometimes because their applications cease to exist. For economic reasons the book will survive better the more thoroughly the new adaptations are carried out and the superfluous parts eliminated. Nevertheless vestigial traces remain.

In such a work as Lamb's "Hydrodynamics", first published in 1879, these processes are well exemplified. It may perhaps be thought that the whole plan of the book is obsolete and that complete rearrangement is necessary. For the first 561 pages it considers only the classical fluid, in which the internal reaction across an element of surface is always normal to the element, and which can slip freely over solid boundaries. The next chapter considers for the first time the real or viscous fluid; and there is a return to classical fluids in the last. Perhaps this is inevitable; the equations of viscous motion are not things one would like to meet at the very introduction to a subject. Further, though classical hydrodynamics is scarcely ever in exact agreement with the facts, it is often an excellent approximation; for example, the whole of the chapters on tidal waves, surface waves, and waves of expansion are still valid in a viscous fluid.

Still, seeing that the fundamental postulates of classical hydrodynamics are wrong, there is a definite problem in explaining why its results are ever right. The attention given to this question is somewhat casual. On p. 106 the inability of a fluid to turn round a projecting corner is attributed to the formation of a negative pressure, instead of to the fact that this is the most striking case where classical results do not give any approximation to the behaviour of a real fluid. The proposition that vorticity in a real fluid cannot originate in the interior, but must be diffused inwards from the boundary, is given in small type on p. 578; I should prefer to state the result in the form of a modification of the circulation theorem, but even in the form given to it by Lamb it could have been made the basis of an explanation of why so much of the earlier part of the book has physical value. Again, much attention is given to vortex motion in Chap. vii; but we might have expected to find somewhere an explanation of how isolated vortices come to exist. Many results are given that have a bearing on these questions, but they are not co-ordinated in such a way as to bring out their fundamental importance.

The process of adaptation to modern conditions has, however, been successful in other matters. The lift of a Joukowsky aerofoil is determined on p. 82; the formula for the resistance due to a Kármán street is quoted; the theory of the effect of viscosity on sound waves is extended. But the most striking additions are the inclusion of an account of the boundary layer theory and one of the effect of compressibility on the motion of fluids around solids, both of which topics are becoming extremely important in aeronautics.

The account of Reynolds's theory of the stability of laminar motion survives; this is remarkable, since Reynolds's discussion proves nothing at all. Orr showed that above a certain Reynolds number some of the types of disturbance, starting small, increase to a maximum, and then die down again. According to Reynolds's method, which considers only the early behaviour arising from a given initial disturbance, these would imply instability; but Orr's discussion of their later behaviour shows that they do not. On the other hand, where Reynolds fails to find his disturbance increasing, stability is not proved, for instability might occur for a different type of initial disturbance.

There is a curious minor vestige on p. 17, where it is stated that the reason for the introduction of the minus sign in the definition of the velocity potential is given in the preface: but the preface that gave it has disappeared in the process of revision. Another is the slip of the pen, $-\omega^2 z$ for 0 on p. 697.

Nevertheless, if we carry our biological analogy a little further, we may predict that the new edition will succeed and probably lead to further successful adaptations. Where a species has material for its existence, even if its adaptation to its conditions is not perfect, it will survive until a better adapted species enters into competition with it; and a book on hydrodynamics capable of competing with Lamb's is unlikely to be produced for some considerable time.

HAROLD JEFFREYS.

Chemistry and our Idiosyncrasies

The Inborn Factors in Disease: an Essay. By Sir Archibald E. Garrod. Pp. 160. (Oxford: Clarendon Press; London: Oxford University Press, 1931.) 7*s.* 6*d.* net.

EVERY one of us is characterised by more or less marked personality as an individual, in addition to belonging to a particular race and having its special attributes. It is permissible to assume that we possess chemical individuality also, that each one of us, varying perhaps on either side of a chemical mean, is built up of slightly different materials from his fellows and leads his own chemical life.

Sir Archibald Garrod, whose well-known book on the inborn errors of metabolism has for many years stimulated thought on this subject, has in his new essay, which had its origin in a Huxley lecture delivered at Charing Cross Hospital, still further broadened the outlook. Bodily metabolism is definitely chemical; our idiosyncrasies, the inborn factors which are apparent in disease, are all intimately connected with the chemical life of their subjects and the chemical structure of their tissues. Since man springs from the chromosomes of the germinal cells, the starting point of the mutations must lie in their variation, and it is difficult to escape the conclusion that upon the chemical structure of the chromosomes depend the structure and form of the creatures which originate from them.

The influences of natural selection which are always at work ensure the survival of helpful mutations and the destruction of those that are detrimental. It is to be supposed that just as, normally, the same chemical reaction is repeated when the same reagents come together under suitable conditions, so it is possible when the conditions are ever so slightly varied for side reactions to occur in greater or less degree. The laboratory experience with catalytic agents, particularly those of an organic nature like the enzymes, affords ample evidence of this variable secondary change, and it is, therefore, not difficult to see how mutations can arise which are in no way restricted to members of a single family or race.

The normal man is one who does not depart in any conspicuous respect from the average of the race: some deviate from the normal to their benefit, others to their detriment. It is highly probable that chemical defects, or errors of metabolism, are common but they escape detection because but few of us, and then only occasionally, are subject to clinical and chemical examination. Our idiosyncrasies, which often affect health out of all proportion to the external causes which provoke them, are undoubtedly due to the disturbances caused by the intrusion of a foreign chemical substance, most often probably of a protein nature. Some of us are hypersensitive to eggs, others to shell-fish, others to strawberries, a few are sensitive to pollen and suffer from hay fever: there is much evidence that all these are inborn and hereditary peculiarities. In such idiosyncrasies it is to be supposed that the poison acts as an antigen reacting with an antibody in the cells of the subject, with the result that histamine is liberated from the damaged cells. What is inherited is an undue liability to such cellular protests.

Metabolism in the body is brought about by ferments activated apparently by specific chemical messengers set free from the ductless glands. Such ferments may be pictured as normally engaged in regular daily work, but they are available, particularly those in the liver, to deal from time to time with unusual substances as best they can. Some day we shall isolate and synthesise the antitoxins just as we have begun to do with the hormones, adrenalin and thyroxin.

We may ask the question: Is the human body a mere machine governed wholly by the principles of physics and chemistry? Whenever it is understood, the answer is in the affirmative, and such work as that of Pavlov has extended our positive knowledge into the field of the control of the nervous reflexes. The growth of science has largely swept away the beliefs of the traditionalist, but vital principles may still lurk in processes not completely understood.

E. F. ARMSTRONG.

Short Reviews

Anthropology and Archæology

Israel: from its Beginnings to the Middle of the Eighth Century. By Prof. Adolphe Lods. Translated by Prof. S. H. Hooke. (The History of Civilization Series.) Pp. xxiv + 512 + 16 plates. (London: Kegan Paul and Co., Ltd., 1932.) 25*s*. net.

"The unique importance of the people of Israel," says M. Lods, "is due to its religion"; but he adds that the study of the origin and development of that religion depends upon the success of a number of preliminary or subsidiary investigations. He therefore surveys the archæology, history and social, cultural and religious development of Palestine under three main heads: first, of the people who inhabited the area before the settlement of the Hebrews; secondly, of the Hebrews themselves before they entered it; and thirdly of the Hebrews after the settlement, when the two streams of cultures had coalesced to produce the characteristic Hebraic system prior to the middle of the eighth century before our era.

It will be obvious that if the field covered by Mr. Lods is one to which the greatest interest is attached owing to its influence in the development of the modern cultures of Christianity and Islam, it is also one into which conjecture enters largely. Upon the major controversial issues such as the ethnic character of the early inhabitants of Palestine and their relations with the Hebrews, the sojourn in Egypt and the Exodus therefrom, M. Lods displays a wise conservatism. He has not allowed himself to be led away by recent tendencies to regard every archæological discovery as a confirmation of the Bible text. The facts are placed before the reader and discussed thoroughly and dispassionately. For this, but not for this alone, M. Lods's book must be accounted a valuable addition to the already extensive literature of the subject.

(1) *Social Anthropology.* By Dr. Paul Radin. (McGraw-Hill Publications in Sociology.) Pp. xii + 432. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1932.) 21*s*. net.

(2) *Economics in Primitive Communities.* By Prof. Richard Thurnwald. (Published for the International Institute of African Languages and Cultures.) Pp. xiv + 314. (London: Oxford University Press, 1932.) 25*s*. net.

(1) The aim of Dr. Radin's textbook of social anthropology is to emphasise man's positive achievement in social organisation and to avoid the undue stress hitherto laid on magic and the irrational side of primitive man's life. He has also avoided general theoretical discussion except in an introductory chapter in which he submits ethnological theories to a very fair and unbiased critical examination. His method has been to set himself a number of specific tasks in description such as the organisation of the State, the organisation of law and custom, economics and industrial life, and the like and to show by a concrete example, the description of a typical tribe or people, how primitive man has solved the specific problem the author has in mind. It is his view that "every type of societal organisation can be encountered among primitive peoples . . . [excepting] representative government".

(2) Dr. Thurnwald, on the other hand, while covering in part the same ground as Dr. Radin, analyses primitive economics by comparative rather than unitary methods, with the view of showing the essential difference in approach to economic problems in a primitive community from that of modern society, owing to the conception of the close interrelation between members and units in a group. It is also his object to show the unreality of the 'three stages' of primitive economic development and the conception of cultural advance along a single line only of previous economic theory, owing to the domination of the views of Darwin and Spencer in the last century. He has brought together a valuable array of facts bearing not merely on food-supply—as he says, rightly, too exclusively the pre-occupation of previous theory—but also on the types of economic life, forms of economic activity, including handicraft, wages, trade, distribution, ownership, etc., and the development of economic methods and simple technical skill, this last illustrated by a series of telling diagrams.

Biology

Scientific Riddles. By Sir J. Arthur Thomson. Pp. 384. (London: Williams and Norgate, Ltd., 1932.) 10*s*. 6*d*. net.

Sir Arthur Thomson divided his last book into four very unequal parts. The first consists of twenty-five brief chapters averaging four or five pages each, most of the titles of which end with a query mark: What is protoplasm? Why do we fall asleep? What are hormones? How does our hair turn grey? The second part contains fourteen somewhat longer chapters discussing such topics as homing, galls, walking in a circle and concluding with an amusing chapter on natural history in everyday conversation which recalls such phrases as 'proud as a peacock', 'raining cats and dogs' and others even more obscure. In Part 3 Sir Arthur treads the borderland between physiology and psychology and gives us six short chapters on animal intelligence, telepathy, dreams, and so on. In Part 4 he sets forth his views on the purpose of evolution, concluding with an epilogue on "The Wonder of the World".

Throughout the volume, Sir Arthur has given full measure of his immense store of biological knowledge, and in his characteristically delightful style.

The book will suggest many problems to the biological student, while for the general reader it shows the present position of knowledge on debated topics, with a wealth of happy analogy and often humorous comment: thus, speaking of protoplasm, Sir Arthur says that it "may be compared to an archipelago with a very large number of small islands on whose multitudinous coastlines there are endless opportunities for brisk trading." Part 4 is a serious contribution to the philosophy of evolution; the remainder is a 'common-place book', for constant reference—and entertainment.

Water-Fowl and Game-Birds in Captivity: some Notes on Habits and Management. By Arthur F. Moody. Pp. 240 + 6 plates. (London: H. F. and G. Witherby, 1932.) 10*s.* 6*d.* net.

THE study of birds in captivity can provide much valuable information, such as the length of incubation and the different stages through which the chicks pass on their way to maturity. In the present volume, we have the author's personal knowledge of how he tended the birds. He gives much information on the construction of aviaries; the varying foods and how to give them; how to handle the birds; how to feather clip and how to pinion them. Under "Vermin" many creatures are included and instructions given for dealing with them. The book ends with a chapter on diseases and how they should be treated.

The volume contains an abundance of information on many different birds and should be welcomed by all aviculturists. Some of the plates are very attractive.

Principles of Soil Microbiology. By Prof. Selman A. Waksman. Second edition, thoroughly revised. Pp. xxviii + 894 + 15 plates. (London: Baillière, Tindall and Cox, 1931.) 52*s.* 6*d.* net.

MUCH additional information has been incorporated in the second edition, but to avoid undue enlargement of the volume the earlier text has been considerably condensed by certain omissions and by the combination of several chapters to avoid unnecessary duplication.

An Introduction to the Scientific Study of the Soil. By Prof. Norman H. Comber. Second edition. Pp. 208. (London: Edward Arnold and Co., 1932.) 7*s.* 6*d.* net.

IN the second edition of this textbook the chief alterations are an expansion of the section on soil microbiology and the re-writing of that dealing with mechanical analysis. Other parts of the book are being brought up to date.

Chemistry

Liesegang Rings: and other Periodic Structures. By Dr. Ernest S. Hedges. Pp. viii + 122 + 8 plates. (London: Chapman and Hall, Ltd., 1932.) 10*s.* 6*d.* net.

ALTHOUGH the Liesegang phenomenon, having engaged the attention of mineralogists, histologists and colloid chemists, has given rise to an extensive and scattered literature, the present work is the first monograph devoted exclusively to the subject. The author gives a full account of the experimental material, beginning with Liesegang's original silver chromate rings and enumerating the numerous other combinations of reactants which have since been found to produce periodic precipitates in certain gels and within certain limits of concentration. He then devotes a chapter to the various theories so far proposed, which have in turn postulated metastable supersaturation, adsorption at the precipitate, membrane formation, variations in the rate of diffusion, periodic coagulation of a colloidal reaction product and periodic inhibition of precipitation by the second (soluble) reaction product as the principal agency. Most of these theories are based on a few, or even on isolated, examples and are incapable of explaining others. This is not really surprising, as there is no *a priori* reason for assuming that the mechanism of periodic precipitation is necessarily the same whatever the reaction producing it.

The author proposes a "comprehensive theory" of periodic phenomena, which however does not at present amount to more than a general qualitative statement of the conditions necessary and (possibly) sufficient for their occurrence, and does not allow one to predict the result in any specific instance.

Interesting chapters are devoted to other periodic phenomena, such as periodic sedimentation and crystallisation, as well as to periodic structures in Nature. A feature of the book is a bibliography containing nearly five hundred references, in which the reviewer has not been able to detect any omissions and has found much that was new to him. The work should stimulate exploration of one of the more curious by-paths of colloid chemistry.

The Structure and Composition of Foods. By Dr. Andrew L. Winton and Dr. Kate Barber Winton. Vol. 1: *Cereals, Starch, Oil Seeds, Nuts, Oils, Forage Plants.* Pp. xiv + 710. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 53*s.* net.

THE name of Dr. A. L. Winton is well known to food technologists for his editing of Leach's "Food Inspection and Analysis" and for his collaboration with Hanausek in "The Microscopy of Technical Products" and with Moeller in "The Microscopy of Vegetable Foods". In this, the first of three entirely new volumes, he has joined with Dr. K. B. Winton, and the work will not in any way replace the earlier books, though it extends and amplifies them; its emphasis is on description, classification, and identification, rather than on the technique of analysis, inspection, or microscopy. It will evidently be considerably larger than the earlier books of which Dr. Winton has been editor or joint author, and, judging by Part I, will form a most comprehensive and well illustrated book of reference.
A. L. B.

Geography and Travel

(1) *Southern Europe: a Regional and Economic Geography of the Mediterranean Lands (Italy, Spain, Portugal, Greece, Albania and Switzerland).* By Dr. Marion I. Newbigin. (Methuen's Advanced Geographies.) Pp. xviii + 428. (London: Methuen and Co., Ltd., 1932.) 15*s*. net.

(2) *The Geography of the Mediterranean Region: its Relation to Ancient History.* By Prof. Ellen Churchill Semple. Pp. ix + 737. (London: Constable and Co., Ltd., 1932.) 21*s*. net.

THESE two volumes, each based on extensive personal travels of the author, are complementary to one another and together will be invaluable to the advanced student of geography.

(1) Dr. Newbigin's volume covers Italy, Spain, Portugal, Greece, Albania and Switzerland and contains also several introductory chapters on the physical geography of southern Europe. In a relatively small compass the conflicting theories of geomorphology are outlined in a way that will be a real help to the student. Climate is treated on a basis of fact free from the simplified generalisations which are too often far from the truth. The various lands are fully treated on a physical foundation and the relegation of statistical matter, except climatic data, to appendices makes the text readable and allows scope for discussion of the broad issues of human response to physical circumstance. There are copious lists of authoritative works and papers and full indications of the maps available for each country.

(2) Prof. Semple's book, on the other hand, deals primarily with the development of human civilisation in the Mediterranean area. The physical background is sketched briefly. Physiographic processes are outside the scope of the book. Climate is considered in its influences, and the sections on vegetation and agriculture are particularly valuable. It is a volume that is packed with information and ideas and every chapter is fully documented. It should become a standard work for geographer and historian alike.

Northern Lights: the Official Account of the British Arctic Air-Route Expedition, 1930–1931. By F. Spencer Chapman. With Additional Chapters by J. M. Scott, Capt. P. M. H. Lemon and Augustine Courtauld. Pp. xvi + 304 + 64 plates. (London: Chatto and Windus, 1932.) 18*s*. net.

FEW arctic expeditions from Great Britain in recent years have succeeded in accomplishing more useful work than that which the late Mr. H. G. Watkins led to East Greenland in 1930. The programme before the expedition was ambitious but much of it was carried out, including the survey of a long stretch of little-known coastline between lat. 64° and 68° N., two traverses of the interior ice cap, the establishment of an ice cap meteorological observatory as well as one on the coast, and various geological and biological investigations.

Many of the details of this work cannot be told in this popular account of the expedition, but enough is said to show that no opportunities were wasted. Two aeroplanes proved useful though they seem scarcely to have given the services that were hoped for. On the ice cap the old-fashioned dog teams were found to be the most serviceable transport. Wireless equipment was a doubtful blessing, in spite of certain advantages.

The story is well told by various members of the expedition. There is no attempt to exaggerate difficulties or to magnify dangers. In fact, the long journeys are described so briefly that they give the reader the false impression of ease. There are several scientific appendices. The book is a notable contribution to arctic literature.

R. N. R. B.

Geology

Petrography and Petrology: a Textbook. By Prof. Frank F. Grout. Pp. xvii + 522. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1932.) 30*s*. net.

THE aim of this book is to study the life-history of rocks rather than their description and classification. To this end, perhaps, the author has subordinated petrography to petrology, the result being that some readers may wish he had omitted petrography entirely. The petrographic parts of the book, especially that on the igneous rocks, are very disappointing when compared with the outstanding excellence of the petrological parts. However, these petrographical portions include many good illustrations well worth studying by readers able to neglect the associated letterpress.

In the petrological sections, which follow the petrographies of the igneous, sedimentary and metamorphic rocks in turn, there is given a really excellent account of modern views on the origin of rocks. An attempt is made to separate fact from theory, and the author is not engaged in boosting a theory of his own—a circumstance to be thankful for nowadays in a work accessible to students.

The modern American points of view on igneous and sedimentary petrology are well known to European geologists, but not so that on metamorphism. In this field it seems that the Europeans are more likely to fulfil the author's aim—interpretation of rocks in terms of history—than are his countrymen.

The sets of mineral tables given are not necessary in a book such as this. A list of selected readings is a welcome feature, though certain omissions, such as Eskola, Sederholm, Sander and others from the metamorphic section, will be noticeable to European readers.

In summary, this book, in spite of its petrographical blemishes, is a very valuable contribution to the general literature on the origin of rocks.

Der Bau der Erde und die Bewegungen ihrer Oberfläche: eine Einführung in die Grundfragen der allgemeinen Geologie. Von Prof. Dr. W. von Seidlitz. (Verständliche Wissenschaft, Band 17.) Pp. ix + 152. (Berlin: Julius Springer, 1932.) 4.80 gold marks.

THIS little book is an excellent introduction to present-day geological thought. The classic question, first answered by Leonardo da Vinci, as to why sea shells are found in the rocks of high mountains, is here put again, and answered on modern lines.

The origin of rocks is lucidly explained on sound uniformitarian principles. It is worth noting, however, that the author directs attention to certain limitations in *Aktualismus*, as, for example, those due to the circumstance that the moist vegetation-covered Europe of to-day furnishes none too reliable a clue to the past.

The main part of the book is concerned of course with the movements to which the earth's crust has been subjected. The contrasts between the rapid, violent movements of the orogenic or mountain-building belts and the slow vertical movements of the more stable areas are developed. But, as we would expect from the author of "Diskordanz und Orogenese der Gebirge am Mittelmeer", we find the importance of the broad epirogenic movements consistently emphasised. The integration of minute movements leads to transgressions and regressions, and thus produces results of fundamental importance for earth history. One of the most interesting parts of an interesting book is that dealing with the detection of epirogenic movements in action at the present day. Further, positive uplift is considered to be the chief cause of mountains: "the mountains grow from the depths, and are still growing".

The book concludes with a table of geological formations, short bibliography, a glossary, and index.

A Textbook of Mineralogy: with an Extended Treatise on Crystallography and Physical Mineralogy. By Prof. E. S. Dana. Fourth edition, revised and enlarged by Prof. William E. Ford. Pp. xi + 851. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 34*s*. net.

CERTAIN additions and much revision, as compared with the third edition of 1922, have been made in this new edition of E. S. Dana's well-known textbook. The chief additions are two. The crystallography section now includes a short account of crystal structure, as revealed by X-ray analysis, which provides a good introduction to an increasingly important branch of mineralogy. A section entitled "Origin, Mode of Occurrence and Association of Minerals" is new to this book, though much of it has appeared in Dana's "Manual of Mineralogy". This section consists of less than twenty pages, so that only a very inadequate summary of mineral paragenesis is presented.

The descriptive part of the book has been revised, the most recent data incorporated, and accounts of more than two hundred new minerals added. Descriptions, short or long, of all known minerals are given. It has been Prof. Ford's aim to give the important facts of mineralogy as known "on January 1, 1932". In this, so far as a work of this kind can be tested, he seems to have succeeded.

Mathematical and Physical Sciences

British Association for the Advancement of Science. Mathematical Tables. Vol. 1: *Circular and Hyperbolic Functions, Exponential Sine and Cosine Integrals, Factorial (Gamma) and Derived Functions, Integrals of Probability Integral.* Prepared by the Committee for the Calculation of Mathematical Tables. Pp. xxxvi + 72. 10*s*. Vol. 2: *Emden Functions: Being Solutions of Emden's Equation, together with Certain Associated Functions.* Prepared by the Commission for the Constitution of the Stars of the International Astronomical Union and the British Association Committee for the Calculation of Mathematical Tables. Pp. viii + 34. 7*s*. 6*d*. (London: British Association, 1931 and 1932.)

FROM 1873 onwards, at irregular intervals, the British Association has published in its annual report various mathematical tables. Unfortunately, these were generally compiled for special purposes, and when regarded as a whole were not well suited for general use. To remedy this defect a committee undertook the heavy task of filling the gaps and (a point altogether neglected in the original form) making them suitable for interpolation. The first volume, begun by R. A. Fisher and completed by J. Henderson, with the assistance of J. R. Airey, L. J. Comrie, A. T. Doodson, A. Lodge, J. Wishart, and others, contains sixteen tables. Some of these are new, and two of them (dealing with tetragamma and pentagamma functions) are the only tables of these functions in existence. The degree of accuracy is high, extending (except in the last) from ten to fifteen decimal places. There is an elaborate introduction filling thirty pages, beginning with interpolation, using Everett's formula and central differences of even orders, for which these tables are specially suitable. After a brief treatment of the better-known functions, the introduction concludes with an extensive account of the properties of certain probability repeated integrals (really Hermite functions) and their applications to statistics.

The second volume is entirely devoted to solutions of Emden's differential equation, which is fundamental in modern theories of the internal structure of the stars, and to certain auxiliary functions. The work, undertaken at the request of Sir Arthur Eddington, was carried out by J. R. Airey, J. C. P. Miller, and D. H. Sadler.

H. T. H. P.

The Queen of the Sciences. By Prof. E. T. Bell. (A Century of Progress Series.) Pp. iv + 138. (Baltimore, Md.: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1931.) 5*s*. 6*d*. net.

THIS fascinating little volume opens with the famous words of Gauss, "Mathematics is queen of the sciences and arithmetic the queen of mathematics. . . ." Prof. Bell takes us from the objects and descriptions of mathematics through the development of systems of algebra, groups and matrices, the Einstein geometry, etc., to Hilbert's logic. Whilst, however, the manifold applications of mathematics are briefly touched upon, especially in the chapter on groups, the treatment rather follows the aim set forth by Jacobi, who, when reproached by the applied mathematician, Fourier, retorted, "The true end of mathematics is the greater glory of the human mind". Indeed, the progress of the century is aptly summarised by the author in the words, "Ever greater generality and ever sharper criticism".

One feels that many of the excellent illustrations are a little too brief to be really effective: just a slightly fuller explanation here and there would not only have safeguarded essential principles being misinterpreted, but would also have made a greater appeal to the lay reader. It is surprising to find no mention of Boole in the chapter on the development of algebra.

The whole book, nevertheless, is extremely interesting, for it tends to broaden the mathematical horizon of the reader, and especially so in the case of a student whose vision has been partially dimmed by the artificial boundaries of examination syllabuses. Here, too, the mature mathematician may derive renewed inspiration. A few references to original sources of some of the topics discussed would have enhanced considerably the value of these.

The Exponential and Hyperbolic Functions and their Applications: a Practical Book for the General Student and Engineer. By A. H. Bell. (Technical School Series.) Pp. x + 82. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 3*s*. 6*d*. net.

THIS little book deals with the practical applications of exponential and hyperbolic functions as required in engineering, physics, etc. Only an elementary knowledge of trigonometry and calculus is assumed. The treatment, whilst not rigorous, is carefully thought out and written. There is, however, a grave danger in not warning the student sufficiently of the necessity of justifying certain operations. Even in subordinating rigour to practical utility, it is nevertheless essential to point out clearly what assumptions have been made and to state that the validity of such assumptions requires further investigation. Especially is this necessary in dealing with series. Yet, on pp. 46–50 it is assumed, without comment, that a circular function is expressible in a valid series, and that the process of differentiation may afterwards be applied to the supposed identity.

The text is well illustrated by fully worked out practical examples, and a fair number of exercises are provided for the student. It is curious to see logh written for $\log_e$. There is an unfortunate misprint on p. 3 where *ex* appears in thick type for e^x.

Advanced Algebra. By Clement V. Durell. Vol. 1. Pp. viii + 193 + xxii. (London: G. Bell and Sons, Ltd., 1932.) 4*s*.

THIS book, originally intended to be Part 4 of the author's "New Algebra for Schools", deals comprehensively with the Higher Certificate requirements. The topics discussed include permutations, combinations, finite series, limits, convergence, logarithmic, exponential and quadratic functions, theory of equations and determinants. The treatment is not only thoroughly sound but also fascinating, the student's interest being stimulated from the beginning. In accord with modern experience, Mr. Durell has not hesitated to introduce calculus methods where necessary. The long, cumbersome and often fallacious methods of the older books have therefore been replaced by valid and elegant proofs. Especially is this manifest in the excellent chapter devoted to the logarithmic and exponential functions, which most teachers will appreciate.

The treatment of limits and convergence, which is often dull, is well adapted to the ordinary pupil, and reveals the author as a practical teacher who knows how to present to young students a difficult part of the subject.

A new book on advanced algebra is long overdue, and teachers will be grateful to Mr. Durell for so ably providing the needed volume.

Recent Advances in Atomic Physics. By Prof. Gaetano Castelfranchi. Approved translation by Dr. W. S. Stiles and Dr. J. W. T. Walsh. Vol. 1: *Atoms, Molecules and Electrons.* Pp. xii + 360 + 12. Vol. 2: *Quantum Theory.* Pp. xii + 400 + 12. (London: J. and A. Churchill, 1932.) 15*s*. each vol.

THE two volumes before us constitute the latest addition to a well-known series dealing with "Recent Advances in Science". Up to the present, we have been able to 'Buy British'; now, if we wish to study "Recent Advances in Atomistics", we have to turn to an English translation of an Italian work, of which three editions have appeared in two years. Well, this is very good free trade and sound internationalism; the book is good of its kind, and may be unequivocally welcomed. It is something of a feat to present in compact form a general introduction to the fundamentals of physical atomic theory, with a discussion on wave motion and kinetic theory, and then to proceed, chapter by chapter, to give succinct accounts of fluctuations, electrons and positive rays, isotopes, X-rays, crystals, radioactivity, nuclear properties, radiation and the quantum theory, spectroscopy, the Stark and Zeeman effects, specific heats, the photoelectric effect, the Compton effect, wave and quantum mechanics, and the new statistics; the whole exposition being completed within the compass of 800 small octavo pages.

It is small wonder that the translators, who have executed their task most competently and critically, decided to omit those sections of the Italian edition which deal with Brownian motion, relativity and astrophysics. It might, in fact, have been better had a few more sections, or some of the more elementary topics, been omitted, and the remainder expanded a little; for modern physical theory is full of subtleties, and a highly condensed treatment is apt to leave a delusive feeling of ease of comprehension that vanishes with a little further thought. This apart, the volumes give an interesting and informative account of modern atomistics, developed in such a way as to make a minimum of demand on the reader's mathematical knowledge; moreover, the author has, very wisely, kept close enough to experimental and technological matters to include brief résumés of such topics as television, supersonics and phototelegraphy.

A. F.

Physical Principles of Mechanics and Acoustics. By Prof. R. W. Pohl. Authorized translation by Winifred M. Deans. Pp. xii + 338. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1932.) 17*s.* 6*d.* net.

Two years have elapsed since the English edition of Prof. Pohl's "Physical Principles of Electricity and Magnetism" was published, and many teachers of physics who were charmed with the novelty of his treatment and the ingenuity of his experiments will welcome this new volume on mechanics and acoustics. The numerous diagrams and illustrations at once attract attention. Most of the figures are based on photographs, and several have been made into silhouettes. It is claimed that this simple method of reproduction indicates whether an experiment is suited to a large lecture-room, as it is then important that the outlines should be clear and uninterrupted. Prof. Pohl tells us that in the Göttingen lecture-room that "troublesome obstacle, the large fixed lecture-table, was got rid of years ago". Small handy tables are set up as required. "The apparatus in actual use at any moment can be made to stand out so that it is easily seen by each member of the audience." Special mention ought to be made of the plates illustrating streamline flow in liquids and gases, and of the exceptionally clear photographs of waves on the surface of a liquid and of sound waves in air by the *schlieren* method.

The subjects treated in the text are those familiar in elementary courses on mechanics, but even the experienced teacher will find much to rouse his own interest and in turn that of his students. The human aspects of the subject are not lost sight of, as for example in discussing the translation and rotation of a man, and the free axes of rotation of human beings and animals. Excellent accounts are given of the motion of liquids and gases, and also of waves and vibrations.

H. S. A.

Numerical Examples in Physics. By Dr. W. N. Bond. Pp. 128. (London: Edward Arnold and Co., 1931.) 4*s.*

This book of some 450 numerical examples in physics, with answers set forth very clearly, covers a remarkably wide range and will be of great use to advanced students of the subject, particularly those reading for a special or honours degree. Nothing like it has hitherto appeared, and the university teacher, who has long felt the want of something parallel to the several excellent books of numerical examples in advanced physical chemistry, will undoubtedly give it a warm welcome.

Dr. Bond is to be congratulated on starting with a section on methods of calculation; and the examples on calibrations, probable error, order of accuracy and curve fitting inculcate the right spirit at the outset. The largest section is naturally on classical electricity where the variety of question is excellent, problems on inductances and ballistic galvanometers and on absolute determination of current and resistance being most instructive. Of particular note is the unique section on atomic physics giving numerical examples on the determination of electronic charge and mass, on Avogadro's number, crystal structure, photoelectrons, the magneton, X-ray scattering, Planck's constant and radioactivity. A few odd questions, not even semi-numerical, have crept into several sections, and might be omitted. Question 132, which deals with special units, has an answer for the mass of the sun of 1·47 kilometres, and question 245 deals with the spectrum produced by a glass prism of refractive index 1·961! But these are mere slips, and there can be nothing but praise for this remarkably comprehensive collection, of the range and quality of which the title gives no indication.

Miscellany

Osiris and the Atom. By J. G. Crowther. Pp. viii + 221 + 4 plates. (London: George Routledge and Sons, Ltd., 1932.) 5*s.* net.

This is a collection of notes and essays of 'popular science' which is actually both popular and on the whole scientific. Mr. Crowther has a chatty, interesting style, the gift of making fairly complex matters readily understood, and a true journalistic instinct for the arresting phrase. The title of the book, "Osiris and the Atom", is an example of the latter; the contest for the soul between the forces of life and death in ancient Egypt is the root idea from which ball games have developed, and the peculiarities of bounding and spinning balls provide useful analogies in the study of atoms. The phrase also expresses aptly the wide range of the book—the great Siberian meteorite, human biology, the structure of wool fibres, modern advances in engineering, Thames floods, terrestrial magnetism, the constitution of the stars, viruses and vitamins.

The author has travelled widely in search of material, visiting Prof. Kulik in Russia for example to discuss the Siberian meteorite. This and the chapter on the structure of wool fibres are especially good, but a few, such as the sketch of "magnetism in the universe", are too superficial to be of real interest. It is curious that the author should have made so elementary a mistake as that on p. 141, where the average air pressure over the oceans is said to be 28 inches. The last article is entitled "Basic English", and is included because the author realised that "a science expert writing for the public has necessarily to make use of a sort of Basic English". The article reads so fluently and naturally that it comes as a shock to find at the end that it is itself written in Basic English.

The Problem of Incentives in Industry: Three Lectures given at the London School of Economics under the Heath Clark Bequest to the National Institute of Industrial Psychology. By Dr. G. H. Miles. Pp. v + 58. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 3*s*. 6*d*. net.

THE three lectures contained in this volume give a popular analysis of the various classes of incentives, including fear and financial incentives, non-financial incentives such as appreciation, knowledge, loyalty, welfare schemes, co-operation, and special incentives like responsibility and promotion which affect those holding management positions. The dangers and limitations of particular types of incentives are discussed and Dr. Miles asserts that the essential problem is that of the development of human power.

Incentives which are designed and applied to increase the general welfare of the worker and his interest in life and work do far more than merely augment output and increase the profits of industry. Those who hold with Dr. Miles that the ultimate purpose of industry is the amelioration of the conditions of life of society in general will welcome the issue to a wider public of this lucid statement of general principles. R.B.

Muscular Work, Fatigue and Recovery: Three Lectures given under the Heath Clark Bequest to the National Institute of Industrial Psychology. By G. P. Crowden. Pp. ix + 74 + 6 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 3*s*. 6*d*. net.

THESE lectures outline certain aspects of the rationalisation of industrial work in the light of the physiological requirements of the human body. They describe in a popular and readable manner the way in which the scientific principles determining human efficiency and fatigue are being elucidated and indicate the contribution which this branch of industrial physiology has to make to human welfare in industry. The survey is not limited to the investigations of British workers alone but also includes a brief description of the Dortmund Institute for the Study of the Physiology of Labour.

The influence of such factors as ventilation, temperature, clothing and food is indicated and this clear and concise statement of the methods of science in this field should stimulate that enthusiastic co-operation among trade unionists, employers, scientific workers, and employees which is essential if full use is to be made even of the knowledge already acquired. R.B.

Philosophy and Psychology

A History of Psychology in Autobiography. (The International University Series in Psychology.) Vol. 2. By Benjamin Bourdon, Harald Höffding, James Drever, Charles H. Judd, Knight Dunlap, C. Lloyd Morgan, Giulio Cesare Ferrari, Walter B. Pillsbury, Shepherd Ivory Franz, Lewis M. Terman, Karl Groos, Margaret Floy Washburn, Gerardus Heymans, Robert S. Woodworth, Robert Mearns Yerkes. Edited by Carl Murchison. Pp. xvii + 407. (Worcester, Mass.: Clark University Press; London: Oxford University Press, 1932.) 28*s*. net.

THE first volume of this work was noticed by us at the time of its appearance. We think that the editor and his co-adjutors were quite justified in their view that the history of recent psychology could scarcely be written, and that indeed a comprehensive statement about present trends in psychology could scarcely be made, without such help as this great work affords. Furthermore, to many readers the personal note which runs through each of these records will prove an aid to understanding, although we must express our conviction that a good deal of the autobiographical detail is superfluous. Still, the work is an important one, and one that reflects credit upon every person concerned in its production.

David Hume. By Dr. B. M. Laing. (Leaders of Philosophy Series.) Pp. xi + 273. (London: Ernest Benn, Ltd., 1932.) 12*s*. 6*d*. net.

AT a time when the extraordinary wealth of our knowledge in all directions threatens our sense of values with conflicting conclusions and assumptions, Hume's scepticism finds a renowed actuality. Dr. Laing's able monograph gives the right historical and philosophical setting of Hume's doctrines, and will no doubt encourage his readers to a closer study of Hume's writings. They will thus find out for themselves that Hume's influence on scientific investigation, or on the theory of it, is strongest where the experimental method and its presuppositions are stressed. But the important part played by mathematics in physical science has set limits to his influence in this direction because of doubts concerning the adequacy of his theory in this respect. T. G.

Berkeley. By Prof. G. Dawes Hicks. (Leaders of Philosophy Series.) Pp. xii+336. (London: Ernest Benn, Ltd., 1932.) 12*s.* 6*d.* net.

THIS is a valuable addition to the series of monographs on the philosophers who have mainly influenced Western thought. Much has been written already on Berkeley; yet Prof. Dawes Hicks succeeds in being both original and interesting in his account of the Bishop of Cloyne. In the exposition of Berkeley's doctrine, he rightly stresses the importance of his opinions about mathematics and the sciences for the understanding of his philosophical views; and the section devoted to Berkeley's place in history adds some fresh material to the valuation of this most fascinating thinker. T. G.

Technology

A Dictionary of Electrical Terms: including Telegraphy, Telephony and Wireless. By S. R. Roget. Second edition, revised and enlarged. Pp. vii+396. (London: Sir Isaac Pitman and Sons, Ltd.; 1931.) 7*s.* 6*d.* net.

So rapid has been the progress made in various branches of electrical science that even scientific workers themselves have sometimes to look up many of the latest treatises published before they find the definition of the term or phrase they are looking for. We have looked up many words such as bel, néper, booster, in this dictionary, and have found clear and satisfactory definitions. Purely trade names of apparatus have been omitted. The use of many technical terms in the electrical industry is almost entirely confined to the United States; but some which originated there are equally used on both sides of the Atlantic; the author gives both. Conciseness has been attained without the sacrifice of intelligibility and the author does not trespass on the function of the encyclopædia or the technical treatise.

In the second edition more than nineteen hundred further expressions have been added and a good many alterations have been made. The author's purpose has not been to compete with the officially established definitions compiled by the British Standards Institution and by the International Electrotechnical Commission. His purpose has been to give explanations rather than definitions. The dictionary should prove useful to many.

Advanced Electrical Measurements. By Dr. William R. Smythe and Dr. Walter C. Michels. Pp. x+240. (New York: D. Van Nostrand Co., Inc., 1932.) 3 dollars.

THE object of this book is to train students so that they may be useful in research, testing and development work. Perhaps it is too much to hope that all the information given can be assimilated in thirty laboratory lessons; but the book can be commended. It is stated (p. 101) that "the growth of modern physics dates from the time of the conception of the electrical theory of matter". If this is regarded as the definition of 'modern physics', evidence can be produced in support of it, but we think that it rather limits its scope.

Comparing this book with similar books published thirty or forty years ago, it will be seen how the methods given of measuring, for example, inductance and capacitance, have improved in the direction of attaining higher precision, but possibly they are less instructive. Students now experiment with various kinds of alternating current bridges, ionisation gauges and hot wire manometers. Photoelectric cells and optical manometers are also used. The mechanisation of laboratory experiments is proceeding so rapidly that there is little time to develop originality. The proof reading seems to have been carelessly done as there are variations in the spelling of the names of continental physicists.

Forthcoming Books of Science

Agriculture, Forestry and Horticulture

George Allen and Unwin, Ltd.—Practical Sheep-Farming, T. C. Norris. *Ernest Benn, Ltd.*—The Garden, W. E. Shewell-Cooper. *Cambridge University Press, Ltd.*—West African Agriculture, O. T. Faulkner and J. R. Mackie. *Martin Hopkinson, Ltd.*—The Apple, Sir Daniel Hall and M. C. Crane; The Garden of To-day, A. Tipping. *Macmillan and Co., Ltd.*—Tropical Soils, Dr. P. Vageler, translated by Dr. H. Greene. *A. Wheaton and Co., Ltd.*—Gardening Science and Biology (Books 2 and 3), Ivan Dowding and H. Bennett.

Anthropology, Archæology and Ethnology

Edward Arnold and Co.—Byzantine Civilisation, Steven Runciman. *B. T. Batsford, Ltd.*—Domestic Utensils of Wood from the 16th to the 19th Century, Owen Evan-Thomas. *Ernest Benn, Ltd.*—If the Blind Lead, M. Alderton Pink. *Cambridge University Press.*—Indo-European Folk-Tales and Greek Legend, W. R. Halliday; Our Forefathers: the Gothonic Nations (vol. 2), Dr. G. Schütte. *Cassell and Co., Ltd.*—The Tomb of Tut-Ankh-Amen (vol. 3), Dr. Howard Carter; An Outline of Italian Civilization, Dr. Decio Pettoello. *Jarrolds, Ltd.*—Backwaters of the Savage South Seas, Evolyn Cheesman. *Sampson Low, Marston and Co., Ltd.*—Incomparable India, Col. Robert J. Blackham; The Martial Races of India, Lieut.-Gen. Sir George MacMunn; Forms and Ceremonies of Marriage throughout the World, E. N. Fallaize. *Macmillan and Co., Ltd.*—A Handbook to the Palace of Minos at Knossos with its Dependencies, J. Pendlebury: with a foreword by Sir Arthur Evans; Ivory Poaching and Cannibals in Africa, J. Molecular Weights of the Blood Pigments of the Invertebrates

BY means of the ultra-centrifugal method, it has recently been shown that the red blood pigment of the annelids is not identical with the hæmoglobin of the vertebrates as was previously assumed, but is a protein more allied to chlorocruorin and hæmocyanin with regard to molecular weight[1]. It was suggested that a comparative study of the properties of the respiratory proteins throughout the animal kingdom might bring to light interesting relationships between the various groups of animals. Such an investigation has now been started, and although so far only some forty species have been studied, a number of regularities have been found which seem to merit general attention.

Four types of respiratory proteins are known from the blood of the invertebrates, a red pigment (erythrocruorin), a green pigment (chlorocruorin), a blue pigment (hæmocyanin) and a pigment of reddish brown colour (hæmerythrin). In the following, only the first three types will be considered.

Of the erythrocruorin type we have found five different forms dissolved in the blood and two forms in blood corpuscles differing with regard to sedimentation constant. Each of the five forms of the first type is characteristic of one of the following groups of invertebrates: oligochæte worms, polychæte worms, gastropods, crustaceans, insects. The two forms of the second type have been found in the erythrocytes of the capitellide and glyceride worms. For the chlorocruorin type only one sedimentation constant has been observed. For the hæmocyanin type we have found six sedimentation constants representing the following animal groups: gastropods, cephalopods (two different constants), xiphosurans, crustaceans (three different constants). Within some of these groups several species have been studied, all of which give the same sedimentation constant with a probable error of about 2 per cent. It is not possible to determine the molecular weight with the same degree of accuracy, but the fact that the sedimentation constants agree so closely makes it extremely probable that the molecular weights are also almost identical.

Among the polychæte worms six species belonging to six different families possess respiratory pigments with the same sedimentation constant, namely, $57{\cdot}5 \times 10^{-13}$ (corresponding to a molecular weight[3] of 2,850,000). Among the gastropods no less than eleven species representing seven different families show the same sedimentation constant of $99{\cdot}5 \times 10^{-13}$ (corresponding to a molecular weight[3] of 5,000,000) and among the crustaceans five species of three families have the constant $23{\cdot}0 \times 10^{-13}$[2]. The lowest sedimentation constant for a respiratory pigment dissolved in the blood is found for the erythrocruorin of the insects (*Chironomus* larvæ). It is only about half that of the constant of the hæmoglobin of the vertebrates and therefore corresponds to a comparatively very low molecular weight. Only a few invertebrates possess red blood corpuscles. So far, we have only had the opportunity of studying the respiratory proteins from two such species. It is noteworthy that in both cases low sedimentation constants were found.

The constancy of the molecular weights of the respiratory blood proteins within various animal groups becomes still more puzzling when the following facts are taken into consideration. The erythrocruorin and the chlorocruorin of the polychæte worms, the erythrocruorin of *Planorbis* and the hæmocyanin of *Calocharis*, the erythrocruorin of the polychæte worms and the hæmocyanin of *Sepia* and probably the erythrocruorin of *Daphnia* and the hæmocyanin of *Eupagurus* have identical sedimentation constants and therefore probably identical molecular weights. The measurement of the absorption of light in the visible part of the spectrum for the blood proteins of the gastropods has further shown that the hæmocyanins of *Helix*, *Paludina* and *Littorina*, which have the same molecular weight, nevertheless are distinctly different with regard to the chemical constitution of the active group of the molecule. A detailed and systematic investigation of the isoelectric points of the respiratory proteins of the invertebrates, now being carried out in this laboratory by Dr. K. O. Pedersen, has brought to light another circumstance of considerable importance. He has found that, as a rule, each species is characterised by a special value of the isoelectric point of its blood pigment. This means that the chemical composition of the blood pigment varies from one species to another, although the mass of the molecule remains practically constant.

It seems, therefore, that only a few molecular masses are stable and that it would depend upon the composition of the molecule with regard to various amino-acids whether one or the other of the different possibilities is realised. The constancy of the molecular weight within a certain animal group would then be a measure of the similarity of certain chemical processes leading to the formation of the respiratory protein.

The regularities in the sedimentation constants which we have found seem to justify an effort to extend this investigation to other species and other groups of animals possessing respiratory proteins.

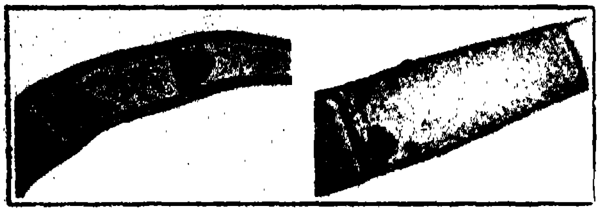
Virus Diseases and Intracellular Inclusions in Plants

VIRUS diseases of both plants and animals are often characterised by the production of abnormal inclusion bodies within the cells of the host. The bodies are usually of more or less spherical form and are protein in nature. Although they commonly accompany virus diseases, they have not been found to occur in hosts infected with any other type of disease, nor are they at all similar to the many intracellular inclusions formed in normal healthy plants.

These virus inclusion bodies have attracted much attention and various theories as to their origin and significance have been advanced. New light was recently thrown on the problem by a study of the response of the cells of several Solanaceous hosts to infection with aucuba mosaic of tomato[1]. The first symptom of the virus attack to become apparent was an increased activity of the cell contents; the cytoplasm became more conspicuous and flowed more rapidly. Then minute particles of protein appeared in the cytoplasm which carried them passively about the cell. These particles aggregated and fused to form a few large masses; the latter ultimately coalescing to give a single mass which became compact and rounded. The mode of formation of these bodies lent support to the view that they are essentially products of reaction of the host cell to the virus. The question then arose as to whether similar effects could be induced in plant cells by physico-chemical means.

The species used in the study of aucuba mosaic disease included, among others, *Solanum nodiflorum*, *S. nigrum* and *S. lycopersicum*. Healthy plants of these three species were treated with small doses of chemical substances known to cause coagulation of protoplasm. The latter comprised mineral acids and salts and organic compounds such as acids, alcohols and alkaloids. Each of these reagents produced, in greater or lesser degree, symptoms similar to the first microscopic evidence of a virus attack: the cytoplasm became increasingly conspicuous and its streaming was accelerated. In some cases, hyaline spheres, similar to bodies which accompany certain virus diseases, were produced. These, however, always proved ephemeral; their movement about the cell might be followed for some hours but suddenly they would be lost into the general mass of plasm.



(*a*) (*b*)

FIG. 1. (*a*) Intracellular inclusions in cells of hair from *Solanum nodiflorum* infected with aucuba mosaic disease. (*b*) Intracellular inclusion formed in a hair cell of *S. nodiflorum* as a result of treatment with ammonium molybdate. Magnification, about 220.

With one radicle it was possible to induce in the cells processes analogous to all stages of an attack of aucuba mosaic disease. Molybdenum, given in the form of molybdic acid, or its ammonium or sodium salts, produced these phenomena, but it has not been possible to reproduce them with any chemically related substance. Soon after treatment began, the cytoplasm became more conspicuous and seemed to increase in volume. It streamed more rapidly, then minute yellowish particles appeared in it and were carried about the cell. When brought together by the flowing of the plasm, these particles coalesced. By aggregation and successive fusions a single large mass was gradually built up. The body, as finally formed, was rougher in outline and slightly more granular than those produced by infection with aucuba mosaic, to which it appeared to be essentially analogous (Fig. 1).

As all produced similar preliminary effects, it is not obvious why the molybdate radicle should induce a much closer imitation of the microscopic effects of the virus than did any other chemical reagent used. If an adequate control could be exercised over conditions within the cell, it is possible that other coagulants might induce similar effects, but this introduces many technical difficulties which cannot at present be overcome.

Recrystallisation Power and Shear Hardening in Aluminium Single Crystals

RECRYSTALLISATION experiments with stretched aluminium single crystals seem to indicate that, for the same amount of shear*, the number of crystallites formed under identical conditions of heat treatment is the smaller the greater the number of slip-planes involved in the distortion.

This behaviour can be readily understood with the aid of the results obtained in a former investigation of the recrystallisation of homogeneously deformed aluminium single crystals[1], in which it was shown (1) that the nuclei of the new crystallites are formed in the locally curved regions of the slip planes (see Fig. 1), which, according to G. I. Taylor and other investigators[2], are brought about as a necessary consequence of the fact that the actual slipping is initiated along limited parts of the planes of slip [which parts may be generally denoted as *Lockerstellen* (Smekal)]; (2) that the number of crystallites formed increases rapidly with the increase of curvature of these locally deformed regions, and therefore with the amount of shear along the slip-planes.

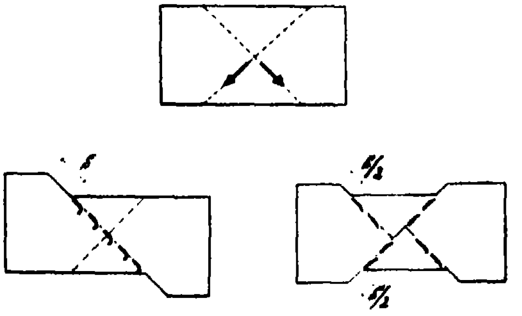

FIG. 1. Diagrammatic representation of locally curved regions along the slip planes.

If now a given 'total shear' is divided over several intercrossing planes of slip, it may be expected to lead to deformed regions of, in the mean, weaker 'curvature' than if the whole shear has taken place along only one such plane. This is schematically illustrated by the accompanying figure (Fig. 1). As a consequence thereof, the number of crystallites formed on recrystallisation is much less in the first case than in the second.

Now it is known from investigations of Taylor[3] and from those of R. Karnop and G. Sachs[4] that during plastic extension or compression of aluminium single crystals, the resistance against slip seems to be not materially influenced (or if so, then slightly increased) by a 'division' of the slip over several planes: in fact, the shear-hardening practically only depends on the 'total amount' of shear. In connexion with this, the possibility arises for aluminium of the *simultaneous occurrence of smaller recrystallisation power and greater hardening* and vice versa.

With the aid of this conception it has been possible to understand in principle the results obtained by several investigators[5], in which this non-parallelism between hardening and recrystallisation power has been demonstrated.

The experiments also permit us to understand why large aluminium crystals, grown by recrystallisation of strained polycrystalline test pieces, seem to favour a position in which a [110] direction is parallel to the direction of straining[6]. This can be related to the fact which has been shown experimentally, that the recrystallisation power is, in general, greatest for aluminium crystals which have been stretched in a direction approaching the [110] direction, the reason for which seems to be that in this direction the probability of the occurrence of *multiple* slip (along 'forbidden planes') is smallest. Therefore it seems probable that on stretching a polycrystalline aggregate, a crystal grain of such orientation will serve as nucleus for the single crystal formed on heating.

I wish to thank Mr. J. J. A. Ploos van Amstel for his valuable help with these experiments. For details I refer to the *Zeitschrift für Physik*, in which they will be published shortly.

Debye's Dispersion of Nitrobenzene

ACCORDING to Debye, dispersion must take place in polar liquids around a frequency ν given by the expression:

$$\frac{1}{2\pi\nu} = \tau = \frac{\zeta}{2kT} \qquad (1)$$

where *T* is the so-called time of relaxation, *k* is Boltzmann's constant, *T* is the absolute temperature and ζ is a constant corresponding to the internal friction which prevents the polar molecules from rotating freely. In the case of spherical molecules, to which Stokes's law can be applied

$$\zeta = 8\pi\eta a^3 \qquad (2)$$

where η is the coefficient of viscosity and *a* the radius of the molecules. The time *T* is of the order of 3×10^{-11} seconds for water and this period corresponds to a wave-length of about 1 cm. In order to bring the dispersion in a region of wave-length more accessible to undamped oscillating circuits, one can dissolve the polar liquids in very viscous nonpolar solvents, as has been shown by Williams and Johnstone[1]. This procedure has another advantage, namely, that of eliminating the spurious effects of molecular association always present with polar substances.

We have dissolved different polar molecules in Shell oil BL 3, which has a coefficient of viscosity of about 5 poises at 35° C., and we have measured the dielectric constant of these solutions for eight wave-lengths between 328 m. and 18 cm.

The small value of the dielectric constant of the oil ($\varepsilon = 2 \cdot 32$) has led us to believe that its molecules were not polar. We verified that the pure solvent showed *no dispersion in the region studied*. For the polar solutions, however, we obtained two regions of dispersion. A typical curve is given in Fig. 1 for two concentrations of nitro-benzene. These two dispersions follow separately and closely the law predicted by Debye.

In order to explain the presence of these two regions of dispersion, we have been led to assume that they correspond to two different types of resisting media in which the molecules can rotate. The region of relatively long wave-length would be brought about by *the friction with which the oil* molecules hinder the rotation of the nitrobenzene polar molecules. The second region would be due to the viscous forces of nitrobenzene itself. Thus our experiments would show that when nitrobenzene is dissolved in viscous oil, some of its molecules form a sort of aggregate while others are relatively free. This view is in complete accord with measurements of the dispersion of amyl and butyl alcohol which we have made and with measurements of this dispersion as a function of the temperature.

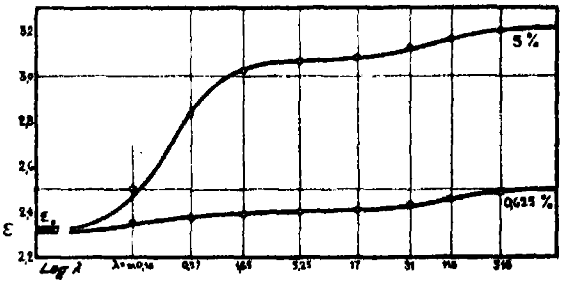

FIG. 1. Dispersion of nitrobenzene at 20°C in Shell oil BL 3.

A more detailed account of this work, which forms the dissertation of one of us (R. L.), is to appear soon in the *Helv. Phys. Acta*.

Reversal of Current in Rectifier Photo-Cells

I HAVE just seen the letter on the above subject by Messrs. H. H. Poole and W. R. G. Atkins in NATURE of January 28. I encountered the phenomenon to which they refer about three months ago when determining the spectral sensitivity of some gold—cuprous oxide—copper cells of the Auger type, but refrained from directing immediate attention to it as it was apparent from an examination of the results that further work was required before a completely satisfactory explanation was forthcoming.

That the cuprous oxide—copper junction is the essential factor in producing the reversal, as suggested by Messrs. Poole and Atkins, is certain, because in cells which I have since been able to examine by the courtesy of the Westinghouse Brake and Saxby Signal Co., in which there is no copper backing to the gilt cuprous oxide layer, no signs of the reversal near 0·6μ are obtained. On the other hand, these cells show a small, but definite reversal in the ultra-violet.

There is no doubt that the wave-length of reversal and the magnitude of the reverse current depend on the thickness of the gold film and also, probably, on the thickness of the oxide layer. The variability of the effect over the surface of the cell described by Messrs. Poole and Atkins suggests that the gold was much thinner than in the cells I have used. The magnitude of the reversed maximum is also apparently greater, which points in the same direction. On this point, however, I would be glad to know if the figures given have been reduced to an 'equal energy spectrum', or if they relate to the intensities obtained in a spectroscope uncorrected for dispersion or for the energy distribution in the spectrum of the source used. I am hoping to obtain, in the not too distant future, the necessary data on the spectral transparency of the gold films and of the cuprous oxide layers to provide a reasonably convincing explanation of the behaviour of these cells.

I note that Messrs. Poole and Atkins found no reversal in a silver-sputtered cell. It may be of interest to mention that with a silvered cuprous oxide cell *without copper backing*, also prepared by the Westinghouse Co., I have found a reversal to occur at the blue end of the visible spectrum. The cell has only recently come into my hands and I have not carried out sufficient tests to see whether any return to the original polarity occurs at still shorter wave-lengths, but the indications are that this is unlikely. These cases differ from that of the gold—oxide—copper cell inasmuch as there is here only one rectifying surface, that between the metal film and the cuprous oxide. I would have preferred to say nothing about the matter until further work had been done towards its elucidation, but as the peculiarities of rectifying cells are apparently exciting a widespread interest, it may be as well to put these cases of reversal on record also.

Reaction Cells in Chain Reactions

THE simplest material chain reaction would be of the type $H + H_2(\text{para}) = H_2(\text{ortho}) + H$, though no evidence has yet been brought forward for its existence. An energy chain would be one in which an excited molecule took the place of the hydrogen atom.

We may define the chain-length by the number of fruitful collisions made by a chain carrier between its production and disappearance, regardless of the total number of collisions. If we consider a mixture of h molecules of the reactant H_2, and a molecules of chain stoppers (for example, an aerosol of antiknock), the average chain-length L is given by the simple probability expression

$$L = \sum_{r=1}^{r=\infty} r \left(\frac{h}{a+h}\right)^r \left(\frac{a}{a+h}\right) \Big/ \Sigma \left(\frac{h}{a+h}\right)^r \left(\frac{a}{a+h}\right),$$

provided that the pressure is so low that the probability of collision of any two molecules is practically independent of their instantaneous position in the vessel considered.

As the pressure is raised, the movements of all the molecules are hindered by the increasing resistance to diffusion; the probability of collision with distant molecules is smaller, and with nearby molecules greater. In particular, for reactions where the average chain-length is large, collisions with the reaction products left in the path of a chain carrier will be relatively more numerous at higher pressures. This may greatly affect the average chain-length.

If D is the coefficient of diffusion of the gas, the mean square displacement of the carrier is given by $\overline{x^2} + \overline{y^2} + \overline{z^2} = 6Dt$, where t is the time elapsed since the chain began. It is thus impossible for the carrier to react with molecules originally outside a cell of radius $2(6Dt)^{\frac{1}{2}}$. If $1/Y$ is the collision frequency, λ the mean free path and d the density, η the viscosity, $D = \frac{1}{3}\lambda\bar{c}$ and $Y = \frac{\lambda}{\bar{c}}$ where $\bar{c}$ is the R.M.S. velocity. After r collisions of any kind whatsoever, $t = rY$ and the radius of the reaction cell is $\lambda(8r)^{\frac{1}{2}}$ and its volume $(8)^{3/2}\frac{4\pi}{3}\lambda^3 r^{3/2}$. Since $\lambda d = \frac{3\eta}{\bar{c}}$ the number of molecules in the cell is proportional to $d \times \frac{r^{3/2}}{d^3} = \frac{r^{3/2}}{d^2}$, which decreases rapidly with increasing density.

The chain carrier has a greater probability of repeated collisions with molecules near the centre of its cell, but the analysis is too long to give here. It follows, however, that if the reaction products, or even impurities, deactivate the chain carrier, or if this has a probability of spontaneous radiation, that the average chain-length will decrease as the pressure rises. The number of chains initiated per second will not in general increase sufficiently with rising pressure to compensate for the decrease in length, and we may expect the rate of such reactions to decrease with rising pressure.

It is tentatively suggested that the upper pressure limit to explosions, discovered in a number of reactions by Hinshelwood and others, may find an explanation in the facts discussed here. It must be noted, however, that in this case we should expect vigorous stirring to increase the average chain-length, and possibly to shift the upper limit to higher pressures. No evidence is yet available on this point.

Dissociation of Acetic Acid in Water

IN the measurements of MacInnes and Shedlovsky[1] and Jeffery and Vogel[2] on the conductivity of acetic acid and its salts in water, which have recently been the subject of correspondence in these columns[3], the most noticeable divergence is in the values for dilute solutions of sodium acetate. Jeffery and Vogel find that their values, after deducting the conductivity of the solvent, are lower than those of MacInnes and Shedlovsky, and that a correction for hydrolysis according to the equation $Ac' + H_2O \rightleftharpoons HAc + OH'$ reduces their figures still further, which leads them to the view that MacInnes and Shedlovsky's values are in error. The reason for this discrepancy is that in Jeffery and Vogel's experiments the hydrogen with which the acetate ion unites comes not from the water but from the carbonic acid present in it. The proper solvent correction for the salt of a weak acid has been discussed elsewhere[4] and can be calculated if the amount of carbon dioxide dissolved in the water is known. Applying it to Jeffery and Vogel's figures on the assumption that their water was saturated with carbon dioxide at a partial pressure of 0·00035 atm. gives values far *greater* than those of MacInnes and Shedlovsky, but the figures obtained in this way are undoubtedly too high, since Jeffery and Vogel's water (like that of the American workers) probably contained saline impurities as well as carbon dioxide. Without precise information on this point the correct extrapolation of Jeffery and Vogel's figures is impossible, but it can safely be concluded that the uncertainty fully covers the discrepancy of 1·6 units between the limiting conductivities derived in the two investigations.

It is to this discrepancy, together with a smaller one in the same direction between the values adopted for the mobility of the hydrogen ion, that the differing values reported for the dissociation constant of acetic acid are mainly due; if both series of measurements are compared on a common basis, the same value of K_a is obtained. This is shown in Fig. 1, in which the logarithm of the constant, uncorrected for activity changes, is plotted against the square root of the ionic concentration, using for both series the common value $\Lambda_0 = 390·59$. The use of this common value neglects the small difference in cell constant bases, which Jeffery and Vogel regard as within the limits of accuracy that they claim for their measurements.

Artificial Control of Sex in the Progeny of Mammals

GENETICS and cytology prove that the sex of the progeny of mammals depends upon the sex of the spermatozoon fertilising the ovum; the ovum itself is not determined as to sex. The 'female' spermatozoon possesses an X-chromosome, the 'male' possesses a Y-chromosome (or no sex chromosome at all), while every ovum has an X-chromosome. Male-determining and female-determining spermatozoa are mixed irregularly in the sperm. Therefore there is only one way of controlling the sex of progeny in mammals, namely, by separating the male-determining from the female-determining spermatozoa.

Spermatozoa with X- and with Y-chromosome are derived from one asymmetric mother $(X + Y)$ cell; it was accordingly natural to suppose that they would carry electrical charges of opposite sign. We accordingly tried to isolate them with an electric current. Most living cells during cataphoresis go to the anode, their surfaces being electrically negative. When we passed an electrical current through horse or rabbit sperm in physiological solution, we found that part of the spermatozoa went to the anode, part to the cathode, while the rest remained some time in the middle in the horizontal part of the Michaelis apparatus.

We have artificially impregnated three female rabbits with three portions of sperm after cataphoresis. The female impregnated with anode spermatozoa produced six young, all of the female sex; the second, impregnated with cathode spermatozoa, produced four males and one female; and the third, impregnated with the central fraction left between the two poles of the Michaelis apparatus, bore two males and two females. So far, this is the only experiment we have carried out on artificial impregnation with anode- and cathode-spermatozoa, and we propose to verify it on a larger scale. However, it is most improbable that the results were due only to chance. The only exception to what we expected, was a female born after fertilisation with cathode spermatozoa, which can be explained by the difficulty of obtaining complete isolation by mechanical means of three varieties of sperm in a Michaelis apparatus.

Capacitance Hygroscopy

I AM obliged to Dr. Schofield for directing further attention to the subsidiary complications of capacitance measurements[1]. As E. B. Moullin says:[2] "We are again and again forced to remember that inductance, capacity, and resistance are attributes possessed simultaneously by all apparatus, and we cannot say that this is an inductance, or that is a capacity with the easy nonchalance of the power engineer". To avoid the accusation of such nonchalance, I used inverted commas for 'capacitance' in my article, made such cautionary remarks as the limits of space permitted, and used the word 'hygroscopy' instead of 'hygrometry' in its title.

Good demonstrations of these complications can be obtained by making various series and parallel connexions between web-tube condensers in air, and then again in water, noting the discrepancies.

It still remains true, however, that with the lay-out described in my article, and under the limitations of use which I there set out, the 'capacitances' which I measured are predominantly due to capacity. For example, the soil-water experiment which I presented was preceded by trials of such condensers in liquids of varied conductivity ; a typical set of readings was as follows :

Air	10	mμF.
Distilled water	44½	,,
Nitric acid, 0·001 per cent.	49	,,
,, 0·010 ,,	56	,,
,, 0·100 ,,	57½	,,
,, 1·000 ,,	59	,,

It follows that such changes in conductivity as are likely to be found in a soil might be expected to deflect the readings by some 5 mμF. at most, whereas the range shown in the actual soil-water experiment was around 50 mμF.

In his numerical examples, Dr. Schofield makes a slight mistake by calculating for resistances in series, whereas these are really in parallel, whether for the case of a web-tube or for a cotton-bale. Resistances of the order of 1,000 ohms in series would obviously dominate the situation, as he says. Actually the correct formula is :

$$\text{'Capacitance'} = \sqrt{C^2 + 1/w^2R^2},$$

and so long as R is not unduly small (for example, when the bale hoops are shorted by a saturated hessian covering) its variations are relatively not important.

In dealing with the physical properties of cotton we are on fairly well-known ground, and experiments on the changes in 'capacitance' of a perforated plate condenser containing cotton have been made similarly to those in which Slater[3] and Goshawk[4] measured the changes of conductivity and of dimensions under various moisture contents. The 'capacitance' changes are directly proportional in outline to the weight changes until very dry conditions are reached, less than 2 per cent of moisture content ; at this point the phase change first discovered by Slater is clearly seen, as if the dielectric constant of the water had there altered to less than half its usual value. But the region of practical working conditions for testing freshly pressed cotton bales (around 8½ per cent moisture content) is far above this, and is equally far below the occurrence of such low resistances in parallel as would seriously deflect the readings.

In these circumstances, Dr. Schofield will forgive me if I venture to disagree with his contention that there is nothing in my article to show that I was not mainly engaged in measuring resistances. The article would not have been published if that were so. Of course, the absence of explicit references therein to elementary trials which were made with non-inductive resistances in circuit, as well as test-alterations of frequency, may well have misled him into thinking that the work was even more amateurish than my apologia indicated it to be.

Is Plasticine Edible?

We were keeping some snails (*Helix pomatia*) without food, under a bell-jar with a wide tubulure at the top ; in the tubulure was a cork bearing a thermometer. We found that the snails ate the cork, so, to protect it, we covered it with a thick layer of red Harbutt's plasticine. To our surprise, the snails ate away a large amount of the plasticine, and produced fæces consisting of plasticine 'mouthfuls' loosely stuck together into irregular cylinders.

At the time of eating plasticine, the snails had been hibernating in a cold store for 18 months, after which they were brought into a warm room and made to emerge by immersion in water. They were therefore extremely hungry. In 24 hours a snail weighing 25 gm. ate 0·5 gm. of plasticine and produced the same amount as fæces. This is as if a 10-stone man were to eat 3 lb. of plasticine in a day.

We have heard many strange stories of substances eaten by hungry snails, but believe this to be the strangest.

Hermaphrodite Frog

A frog with abnormal genitalia was brought to my notice during class work. A pad was present on the forefingers as in a normal male. The kidneys were longer than in a normal frog and reminiscent of those of the newt. The right testis was normal but the left had embedded in it very distinct ova. Vasa efferentia arose from both testes. The left oviduct was similar to that of a normal female but the right was thinner and only vaguely connected with the cloaca. The mesonephric ducts were normal but apparently lacked vesiculæ seminales.

The specimen, with others, was collected from a pond near Radley College, Abington, Berks, and it will be interesting to discover if others occur in this area.

Caution in Christening

The names of public characters should be chosen circumspectly. To christen the antiscorbutic agent (granted, that we at last have it in hand) *ascorbic acid* is to do it slight justice—even to rob it of the public appreciation it deserves. The name, in fact, is a scurvy one : neither has it obvious significance nor can it well be transposed into either French or German ; in no tongue will it have lilt.

Skorbut, whence scorbutic, apparently is of low German or Dutch origin. Why not call the spade a spade : simply, *antiscorbutic acid*—antiskorbutsäure—acide antiscorbutique ? I hope the distinguished magician who has so deftly conjured one of the great mysteries of our being into tangible form will accept the suggestion.

Henry E. Armstrong.

Research Items

Omaha Secret Societies. Dr. R. F. Fortune in a study of the Omaha and their secret societies (Columbia Univ. Contrib. Anthrop., vol. 14) supplements, expands and sometimes corrects the material of previous observers—in such matters, for example, as the hereditary character, at disposal in the male line, of membership of the different classes of Omaha society, of chieftainship (excepting the lesser chieftainships) and of membership in the secret societies. Consequentially it may be shown that Omaha society is essentially aristocratic under democratic forms. The Omaha have four important doctoring societies, each under its own special supernatural patron, each with its own individual mode of curing, and its own special group of disorders. The first society, however, is peculiar in having two supernatural patrons, the grizzly bear and the rattle-snake, each of which has its separate set of votaries dealing with its own group of disorders. The two sets of votaries, however, have their method of healing in common—extraction of the illness from the body of the patient by sucking. The grizzly bear votaries treat rheumatism and local body pains, except stomach trouble, which is the province of the rattle-snake votaries, this disorder being supposed to be due to rattle-snake poison in the stomach which has been wafted through the air by 'influence'. The second society is the ghost society, of which the patrons are the human ghosts. They treat delirium, epilepsy and mental disorders, their method of healing being the sprinkling of warm water. The third society is that of the buffalo patron, which heals wounds only by blowing water from the mouth over the part affected. The fourth society, which has a water monster patron, treats any ailment not pre-empted by the other three, as well as specialities, such as child-birth. This society works by sleight of hand, removing material objects from the part in which the disease resides.

Eyes and Colour Change. At the December meeting of the American Society of Zoologists, Prof. Lloyd M. Bertholf read a paper in which he described the influence of eye extract upon body colours (Science Service, Washington, D.C.) He found that eyes acted as glands, secreting a substance which caused contraction of chromatophores. The hormone was found in the eye-stalks of Crustacea, but it was effective in producing colour changes when injected into the body not only of Crustacea but also of frog tadpoles and of several species of fishes.

Bird Migration in Tropical Africa. Little has been written about the regular movements of birds in the tropics of the Old World, so that the account of migration by James P. Chapin in his great work on "The Birds of the Belgian Congo" is of unusual interest (*Bull. Amer. Mus. Nat. Hist.*, 65, 1932). There are regions in Africa where bird life shows little change throughout the seasons, but the moist Congo basin lies between two wide drier areas of Africa from which the birds have good reason to move in the unfavourable season. The migrants from such African areas enter the Congo by the northern and the southern borders ; some even come from Madagascar. But the migrations are complicated by the arrival of many individuals from Europe and Asia which seek refuge from the northern winter, and by a certain number of native water birds which vary locally in abundance according to the level of the great rivers. In addition, there are birds of passage from Europe and Asia which tend to pass through the Congo to South Africa. There the conditions appear to be so favourable to some northern species that they have been found breeding in South Africa, and the presence of distinct geographical races of Eurasian birds points to a suitability of habitat which has led to the establishment of migrating individuals in earlier times.

Functions of Radiation in the Physiology of Plants. Under the above title, two papers (*Smith. Misc. Coll.*, vol. 87, Nos. 13 and 14) describe recent work from the Division of Radiation, Smithsonian Institution. A more than usually elaborate apparatus for growth of plants under controlled conditions with special attention to radiation is described in detail (F. S. Brackett and E. S. Johnstone, No. 13). Temperature, humidity, gas concentration and pressure and aeration of nutrient solution, are fully controlled. Either lateral or overhead illumination may be obtained at will. Standard incandescent filament lamps used in conjunction with various filters, or electric discharges through gases may be used as sources of radiation. The latter method provides sources of monochromatic radiation otherwise difficult to obtain. Using the technique described, an examination of the effects of infra-red radiation upon tomato plants has been made (E. S. Johnstone, No. 14).

Improvement of Colour of Apples. A method of improving the colour of dessert apples after picking, by means of a process termed 'sun-dewing', is described by H. Goude in the *Journal of the Ministry of Agriculture*, vol. 39, p. 904. The process, which has been practised for many years at the Burlingham Horticultural Station, is very simple, entails no expensive apparatus and, at the same time, adds greatly to the commercial value of the fruit. The maximum cost may be roughly estimated as 1*s.* per cwt. Cox's Orange Pippin, Ellison's Orange, Allington Pippin and Laxton's Superb are some of the varieties mentioned which have been treated successfully, but apples with a greasy skin do not respond and others, such as Worcester Pearmain and Norfolk Royal, are apt to develop a bleached appearance. The fruit, eyes upward, is packed on trays lined with clean wood wool or moss and placed in an exposed position preferably facing south, but protected from birds, slugs, etc. Water is then sprayed over the fruit, which must not be allowed to become dry at any time during the treatment or shrivelling will set in. Exposure at night forms part of the treatment; although damage from frost has never been experienced, if frost occurs it should be washed off the fruit before the sun's rays reach it. Colouring will probably be effected after ten days, and the resulting fruit can then be stored in the usual way. The keeping quality of 'sun-dewed' apples is improved, and further, they show a pronounced resistance to store-rot troubles.

Submarine Valleys. Submarine valleys are known on many continental shelves and the use of echo sounding has facilitated their accurate charting. Prof. F. P. Shepard discusses their origin in a paper in the

Geographical Review for January. Such valleys have been variously attributed to river-cutting with displacements of the continental borders, to faulting, to submarine currents or to collapse of submarine solution channels. Prof. Shepard suggests that the chief cause has been originally river action followed by submergence in the long past, after which the valleys have been filled in by sediment during the cutting of the present continental shelves and then reopened from time to time by submarine landslides of the accumulated deposits. This theory provides an explanation of the fact that several of the valleys do not penetrate to the coasts as submarine estuaries. The landward part of the valley would be less liable to landslides than the steeper seaward end; or furthermore, the landward end would be liable to disappear, as a valley, in the cutting out of the continental shelf. Valley-free shelves occur in those areas where landslides have not occurred owing either to the slope being too gentle or to rapid cementation in calcareous sediments.

Particle Size and X-ray Spectroscopy. In a limited number of elements a lower intensity of the $L\alpha$ doublet has been observed when the element was in the form of metallic powder rather than a polished plate or even an oxide, and the effect is present to a very much less extent with K-radiation. Fonda (*J. Amer. Chem. Soc.*, Jan.) shows that the effect occurs under the usual experimental conditions, when the emitted X-ray beam is examined at a different angle from that made by the exciting beam of electrons. These irregularities, which may introduce serious errors in applications of X-ray spectroscopy to quantitative analysis, are a consequence of too large particle size, which brings about an abnormal absorption of the emitted radiation, particularly when it is in the longer wave-length range. X-radiation is excited throughout a certain depth of material, depending on the penetration of the electrons, and consequently encounters, in emission, a corresponding amount of absorption by the material itself. If there are any irregular protrusions in the surface which lie in the path of the beam under investigation, then the radiation is subjected to additional absorption as it passes through them. The decrease of intensity was found to be proportional to the magnitude of the surface irregularities in the target and to the coefficient of absorption of the target material. Attention must, therefore, be paid to the fineness of the powdered samples, particularly when $L\alpha$-radiation is used.

A New Temperature Recorder. Dr. W. Cawood and Mr. H. S. Patterson, of the Department of Inorganic Chemistry of the University of Leeds, have designed, and Messrs. Reynolds and Branson Ltd., Leeds, have put on the market, an accurate temperature recorder possessing many advantages over existing types. It consists of a special mercury thermometer, an image of which is projected on to a strip of bromide paper rotated either by clockwork or by a synchronous electric motor. The drum carrying the bromide paper is mounted in a light-tight case which can easily be detached and taken to the dark room for development. Each strip is 24 in. long, corresponding to 24 hours running, and by means of spare drums a continuous record may be obtained. The main advantage of the instrument over others of a like design is that both the top edge of the mercury meniscus and the engraved divisions on the thermometer are photographed simultaneously. The divisions of the thermometer appear as parallel lines which are cut off by the top of the mercury thread. Thus the only calibration required is that of the thermometer, and moreover, any vibration or jolt will not throw the instrument out of adjustment, but will merely displace the image. The accuracy and range depends upon the thermometer which is used; 0·01° may be easily obtained over a range of 3° or 4° C., or 0·1° over a range of 30° or 40° C., but this range can be enlarged by a simple modification of the apparatus. It will be appreciated that an accuracy of 0·01° is difficult to attain on any other temperature recorder and involves the use of apparatus both complicated and costly.

Astronomical Topics

The Sothic Cycle. Mrs. A. S. D. Maunder has published a paper on this subject (*J. Brit. Astro. Assoc.*, Jan.). The paper was written in answer to M. Sundaram Ayyar, who asserted the identity of the Egyptian Sothis with Arcturus, called Svati in India. It examines the sources of early Indian astronomy, and conjectures that the traditional author of the Siddhantas, Ashura Maya, may be a corruption of the Persian deity Ahura Mazda, and that these astronomical tables came from Persia. Mrs. Maunder gives a high valuation of the accuracy of the early observations made in Persia, but a much lower one to contemporary observations in Egypt, considering that the Egyptians could not then have observed the culmination of Arcturus with any accuracy. The well-known fact that the Nile flood comes close to the heliacal rising of Sirius leads her to adhere to the traditional view that Sothis is Sirius.

Direct Observation of Solar Prominences. The observation of solar prominences has hitherto only been possible by the aid of spectroscopes with widened slits, or of spectroheliographs, except during moments of actual totality in solar eclipses. In 1931, however, at the Pic du Midi, M. B. Lyot succeeded in making direct observations of prominences without such aids, owing to the extreme clearness of the atmosphere which eliminated much of the diffused sky light in the neighbourhood of the sun. On clear days, the intensity of this light was only 5 millionths that of direct sunlight, and prominences could be both seen and photographed even without the aid of a colour filter. The use of a simple red glass filter enabled them to be seen with ease even on poorer days. M. Lyot has repeated these experiments at Meudon, and described the results recently (*C. R. Acad. Sci.*, Nov. 21, 1932). Owing to the poorer atmosphere of Paris, a different form of filter was required. The author has devised one consisting of a tube filled with a slightly acidified solution of neodymium nitrate and closed at one end with Schott *RG*2 glass (the other end being of plain glass). In addition to some unimportant light in the infra-red, this filter transmits light in a narrow band (about 80 A.) containing the $H\alpha$ line. With its aid he has been able to photograph prominences at Meudon even on misty days, with an exposure of only one second for a solar image of 8 cm. diameter.

Relation of Food to Disease*

MANY diseases, ranging from different types of poisoning to deficiency diseases, are caused by defects or impurities in the food supply of a population: at times they may even occur in epidemics. Cure may be brought about by changing the food supply or by adding a missing factor to the diet; in other cases, only medical treatment is of value. Prevention, as always, is better than cure. With an adequate dietary of pure foods, most of these diseases can be abolished or their incidence greatly reduced. A review of the disorders associated with the ingestion of food, which was given by Mr. S. Dixon, the public analyst of the City of Cardiff, to a joint meeting of the South Wales Section of the Institute of Chemistry and the local section of the Society of Chemical Industry, at Cardiff, in February 1932, has now been issued as a small brochure and provides a useful and interesting summary of our knowledge of the subject.

The deficiency diseases are first briefly referred to, especially those associated with a deficient intake of one or other of the vitamins, such as rickets and scurvy, or in other countries beriberi and pellagra. Chemical poisons of non-bacterial origin may be inorganic substances which have gained access to the food through faulty methods of manufacture, or organic compounds present in certain animals or plants which are not foods in the true sense but may be consumed through inadvertence. Mushroom poisoning still occurs, although epidemic ergotism is now rare. An epidemic of the latter, however, occurred in England five years ago among Jewish immigrants from Central Europe who lived on rye bread.

The chief metallic poison which may contaminate foodstuffs is arsenic, which may find its way into the food through the use of material prepared with the aid of impure sulphuric acid: it may also be found on fruit which has been sprayed with an insecticide containing lead arsenite and once was inadvertently used as a dusting powder for boiled sweets. Antimony, lead and zinc may also produce poisoning, but small quantities of tin and copper do not usually have any deleterious effects.

Various diseases are conveyed to human beings by food which contains pathogenic bacteria. Milk may be responsible for the spread of typhoid, scarlet fever, diphtheria, bacillary dysentery, tonsillitis, and undulant fever. Surgical tuberculosis in children, when caused by bovine tubercle bacilli, is due to the ingestion of these organisms in the milk. Other articles of food which may be infected with the organisms of infectious diseases are ice-cream, meat, and shell-fish, especially mussels and oysters. Another group of diseases is due to contamination of the food with organisms of the *Salmonella* group, dysentery bacilli or *B. botulinus*. These are classified under the term, "Bacterial Food Poisoning". It is not considered that 'ptomaine' poisoning has any scientific basis, although two types of poisoning are due to toxins formed by organisms, namely, botulism, and a rare form of mussel poisoning which appears to be due to chemical poisons elaborated in the shell-fish by the vital activity of bacteria derived from sewage-contaminated surroundings.

Animal parasites are not responsible for much disease in Great Britain, though they assume greater importance in the tropics and in countries where food is imperfectly cooked. Tapeworm infestations, in their larval or adult forms, and trichinosis, from the ingestion of infested pork, are the commonest.

In conclusion, attention may be directed to food idiosyncrasy, which illustrates in the modern manner that what is one man's food may be another man's poison.

---

* "The Relation of Food to Disease". By Stanley Dixon. Pp. 38. (London: The Institute of Chemistry of Great Britain and Ireland, 1932.)

Chemistry of Australian Timbers*

MESSRS. W. E. COHEN, A. L. Baldock and A. G. Charles have produced a useful pamphlet on the chemical composition of the woods of the ironbark group of eucalypts, which constitutes Technical Paper No. 4 of the Division of Forest Products of the Council of Scientific and Industrial Research. The important species upon which the study was based are the ironbarks *Eucalyptus sideroxylon*, *siderophloia*, *crebra* and *paniculata* together with a less important species *E. fergusoni* and the grey gums *E. propinqua* and *E. punctata*.

The first four mentioned are the commercially important ironbarks and have a wide geographical distribution, the group spreading over the eastern States, Queensland, New South Wales and Victoria; the remaining species have a more restricted distribution. The eucalypts are in great demand for all types of heavy structural works. They are used in railway and bridge construction, shipbuilding, coach and waggon building, houses, railway sleepers, wharf decking and so forth.

In a foreword to the pamphlet, Dr. Boas, chief of the Division of Forest Products, states that in this paper the authors describe the first extended chemical study of a group of timbers of the genus *Eucalyptus*. The importance now being attached to this chemical study of wood is summarised as follows: "There is a general trend in forest products research towards utilising wood substances after some form of chemical transformation. Other investigations involve altering the physical characteristics of wood to increase its resistance to fire, and to reduce in seasoned timber the absorption and loss of moisture with consequent shrinkage and swelling. Such proposals and those associated with converting wood into paper, artificial silk, lacquers, etc., must have their foundation in a fuller knowledge of the chemistry of timber. This Division has consequently planned work in this field, almost untouched as far as Australian timbers are concerned."

At present, in the systematic study of the chemistry of the timbers, consideration is being given to those groups containing woods, which, in addition to being very similar in general characteristics and therefore easily confused, are not easy to separate by means of their anatomical features. The object of the investigation discussed in the pamphlet, which was commenced in July 1930, was to obtain data on the proximate composition of sound, mature, true wood from authentic samples of the timbers with the view of studying (1) their general composition; (2) the possibility of constancy of chemical factors within a species, and of regular differences between species, so that these factors might be used in the identification of the timbers; (3) the variation of chemical composition within a tree; and (4) the applicability to Australian timbers of existing standard methods of wood analysis.

---

* Commonwealth of Australia: Council of Scientific and Industrial Research. Pamphlet No. 32, Part 2. (Melbourne: H. J. Green, 1932.)

Some striking differences in chemical composition have been revealed between the eucalypts examined and the hardwoods of North America for which analyses are recorded. The eucalypts may be said to be characterised by the presence in their vessels, rays, and fibres of gum-like, brittle, extraneous substances which are not soluble in the usual organic solvents, but are readily soluble in alkaline solutions. The eucalypts possess definitely lower contents of cellulose and total pentosans than North American hardwoods do, even though due consideration is made for differences in extractives. It is interesting to note that the lignin content is much the same for both series in spite of the different analytical methods used, and, if it is assumed that the apparent lignin content of the North American woods will be decreased by initial treatment with $N/8$ sodium hydroxide, then the figures will probably be nearly the same.

The present study has revealed the fact that the standard methods for wood analysis employed in other countries are not readily applicable to the eucalypts. Here again the extraneous substances have played an important part. Their brittle nature has served to indicate that the so-called standard method of sampling wood in the form of sawdust, powder, etc., is inaccurate. Their insoluble nature and resistance to acid hydrolysis have resulted in the failure of the usual method for indicating the correct lignin content of woods. Consequently, the methods of analysis have had to be considerably modified, and it would appear that these modifications are applicable to wood analysis in general.

Developments in Highway Research

PROF. STEINBURG of University of Maryland gave a radio talk on January 13 under the auspices of Science Service over the Columbia broadcasting system on developments in highway engineering. Of the many problems confronting the engineer, the one in which the public is most interested is that of safety in the streets. In the United States there is a rapidly increasing motor-car annual toll of about 34,000 lives and a million injuries.

Although primarily an engineering problem, highway safety is very considerably affected by the psychological, as well as the physical, demands upon the driver of a motor-vehicle. Recent research has shown that the human factor is responsible for approximately ninety per cent of motor-vehicle accidents in the United States and that the causes attributed to defects in the highway or the vehicle are of small relative importance. A psychological study was recently made at the Iowa State College of 2,000 drivers. They were tested on a specially constructed outside road as to their action and reaction when lights, signals, direction and warning signs were encountered. The results showed that the drivers could be divided into three classes. The first class consists of the 'accident free' drivers and comprises about seventy-five per cent of those tested. This group causes little trouble in any ordinary circumstances. The second group numbers about twenty per cent of the total and contains the 'accident liable' drivers who give trouble from various causes. Some are irresponsible, some are preoccupied through illness or personal affairs, while others are careless. Their failure arises either from heredity or environment and renders it necessary for the highway engineer to provide fool-proof roads. The third small group and the individuals who compose it generally suffer from some defect such as colour blindness, restricted field of vision, double vision of a single object, or extreme nervousness and poor co-ordination. Now as half the total accidents are caused by only about seven per cent of all drivers, it is obvious that special consideration has to be given to this third class.

A recent study of road signal signs shows that in the central west of the United States they are well standardised as to form, size, colour and location, while in the east there is much diversity of practice. Delaware has recently experimented with a pictographic signpost showing the direction of the roads on the marker by drawings similar to those used in Canada. They were found much clearer and more easily understood than the type in general use. Experiments have shown that arrow pointers are superior to the marks *R* and *L* for indicating right and left, as many people are momentarily nonplussed when told to go to the right or to the left; and it has been found that for road markers, canary yellow is much the best colour, as it stands out well from surrounding objects at all seasons of the year, and, as the human eye is very sensitive to yellow light, it is good for low illuminations.

Experiments were quoted showing that the capacity of a two-lane road is 1,000 vehicles per hour, for a three-lane road it is 2,000 and for a four-lane 3,000 vehicles and that the risk of accident is greatest with the three-lane road. This research in highway engineering has been a valuable one and has led to many practical changes which will result in a very large saving of both highway funds and vehicle operating costs.

Nomenclature of British Marine Mollusca*

IN revising the "List of British Marine Mollusca" for his presidential address to the Conchological Society, Mr. R. Winckworth has, admittedly, attempted a difficult task which is bound to bring forth criticism. A new list was certainly wanted, for it is more than thirty years since a special committee of the Conchological Society published one (*J. Conchol.*, 10, No. 1. Jan., 1901) which is now in many ways out of date. All workers on the group will be grateful for this well-authenticated revision, compiled by one who is an authority on the subject.

The greatest difficulty which one meets in deciding correct nomenclature is not now so much the weight of old literature which has to be perused in order to ascertain which authority has priority, heavy as this burden is, but the keeping up to date with new work constantly appearing which brings forward new facts necessitating alterations. Thus every day new data turn up, old names must be abandoned and new relationships admitted.

---

* "The British Marine Mollusca", by R. Winckworth. *Journal of Conchology*, 19, No. 7, June 1932 (Presidential Address, Oct. 1931).

One of the obstacles to be met in making a natural classification is the absence of detailed knowledge of the life-histories of the various molluscs. A thorough acquaintance with the eggs and larvæ at all stages would do away with much that is obscure. Mr. Winckworth in his preliminary remarks refers to work lately begun at the Marine Biological Laboratory, Plymouth, which is an attempt to supply this want. Already it is proving useful in determining the natural relationships of gastropods.

Another serious disadvantage is the inability of workers in general to see a large enough series of shells. Work such as has lately been published by Mr. John Colman ("A Statistical Test of the Species Concept in Littorina". *Biological Bulletin*, 42. No. 3. June, 1932) is valuable.

In 1931 the Marine Biological Association published a second edition of the "Plymouth Marine Fauna" in which the nomenclature of the Lamellibranchiata and to a less extent the Gastropoda were revised by Mr. Winckworth. In his new list, however, quite a number of the names (family, genus and species) have been changed; for example, *Erato lævis* altered to *Erato voluta* on account of a few months priority of Montagu over Donovan: *Psammosolen candidus* (Renier) altered to *Solecurtus scopula* (Turton) and many others. This is a good example of the difficulties encountered in undertaking such an arduous piece of work.

The "List of British Marine Mollusca" can be purchased from the Secretary of the Conchological Society of Great Britain and Ireland, Manchester Museum, The University, Manchester, or from Messrs. Dulau and Co., Ltd., 32 Old Bond Street, London, W.1, price 9*d*.

The Iron and Steel Industry

THE last of the present series of lectures on industrial affairs at the Imperial College of Science and Technology was delivered on February 23 by Sir William Larke who took as his subject "The Iron and Steel Industry". He pointed out that although the smelting of iron ore with charcoal has been carried on since 2500 B.C. or even earlier, smelting with coal or coke was not established successfully until 1730–35. Between 1740 and 1840 the production of pig iron in Great Britain rose from 17,350 tons to 1½ million tons, but it was not until about 1860 that the 'iron age' gave place to the 'steel age'. This change was signalised by the rapid development of railways and by the substitution of steel for iron in shipbuilding. As the birthplace of the iron and steel industries and of the blast furnace, the steel furnace and the rolling mill, Great Britain was for many years the leading producer, but owing to intensive developments in other countries, especially the United States and Germany, it had fallen to third place in respect of pig iron production by 1913.

After the War, the important iron ores of Lorraine came under French control, and when Germany recovered her economic freedom in 1925 the products of this district were thrown upon the world markets. In the meantime, other countries were building up iron and steel industries and Great Britain was practically the only accessible free market for the huge surplus Continental production. It is noteworthy, however, that if the world consumption of pig iron had continued to increase at the average rate of 6 per cent a year which was maintained between 1810 and 1910, it would have reached 186 million tons in 1932: the actual production in that year was only 38 million tons and the productive capacity 120 million tons.

Sir William Larke believes that we are suffering to-day from under-consumption rather than from over-production. The organisation of the German iron and steel industry on a national basis was followed by the formation of a Continental steel cartel, but with contraction in demand, prices could not be maintained and fell eventually below the cost of production. The cartel ceased to function in 1930. The British market was the cockpit in which the price warfare was waged: after the introduction of protection Continental producers were endeavouring to maintain their sales at prices as much as 40 per cent less than the cost of production.

It might be supposed that the fall in prices of iron and steel would react to the advantage of those industries which use these commodities as their raw materials. Under pre-War conditions, when the general demand for goods was expanding rapidly, this would have been true, but it must be realised that these conditions no longer prevail. Undertakings involving the large-scale consumption of steel, for example, shipbuilding, are actually held back lest a further fall in price should render the enterprise uneconomic at the new level. In fact the present economic situation is probably unique in the history of mankind, and the solution of its problems cannot be found on pre-War lines. In Great Britain steps have been taken and are being taken towards the establishment of a strong national organisation of the iron and steel industry. Unrestricted competition, which was formerly advantageous in promoting efficiency and stimulating enterprise, now requires to be strictly limited. Since what we call the iron and steel industries really consist of about a dozen related industries, there are many conflicting interests to be reconciled; but much has already been done in the establishment of co-operation not only at home, but also at Ottawa with the Dominions.

The next step is international co-operation to regulate production in relation to demand and to stimulate consumption. So long as the British market was open, little could be done in this direction. The adoption of a protectionist policy has, however, brought about conditions favourable for negotiations with foreign producers, and our co-operation is now being actively sought. In fact, at the beginning of this month an agreement was signed for a new cartel, which is to deal with export trade only. This cartel will be maintained only if sales agreements can be made and a stabilisation of price levels achieved.

In conclusion, Sir William Larke referred to the prospects for scientifically trained men in industry.

In the iron and steel industry there is scope for chemists, physicists, metallurgists and engineers—provided that they have the gift of establishing human relations. In industry, the understanding of one's fellow men is more important than technical knowledge. Sir William decried the modern pose that enthusiasm is 'bad form'. We live in an age of great difficulties and responsibilities, but also of great possibilities—and we need all the enthusiasm that we can muster.

Flora of East Anglia

"THE East Anglian Flora—a Study in Comparative Plant Geography" is the title of the presidential address by Prof. E. J. Salisbury to the Norfolk and Norwich Naturalists' Society, reprinted from the Society's *Transactions* (vol. 13, pt. 3, 1932, pp. 191–263).

While treating specially of the flora of East Anglia, Prof. Salisbury has extended the scope of his address to include a survey of the major problems of geographical distribution in Great Britain as a whole. Eight components are recognised in the British flora, four of which are further subdivided into eleven constituent elements, and stress is laid upon the importance of viewing these groups in relation to the distribution of the species on the continent of Europe. The largest components are the southern, the oceanic and the continental. The majority of the southern species exhibit in Britain a diagonal limit running in the south-west—north-east direction, indicative of their comparative intolerance of oceanic conditions, while in contrast to these, most of the oceanic species show a diagonal limit passing in a south-east—north-west direction. The continental component includes the steppe species, many of which are located in East Anglia, and it is held that their occurrence there is correlated with a combination of low rainfall and favourable edaphic conditions.

Two strikingly contrasted climatic areas are found in the East Anglian region, in which marked difference in rainfall is accentuated by differences of soil and topography, resulting in the juxtaposition of both continental and oceanic species. The general conclusion is reached that climate is the most important factor determining the distribution of plants in Britain, though evidence is adduced in certain cases to show that soil preferences and the competition factor may act as modifying influences.

A noteworthy feature of the paper is the large number of maps, 106 in all, clearly illustrating the range of individual species within the British Isles, while numerous photographs are included depicting certain interesting species in their natural habitats. Copies of the paper (price 5*s.*) may be obtained from Dr. S. H. Long, 31, Surrey Street, Norwich.

University and Educational Intelligence

BIRMINGHAM.—The annual meeting of the Court of Governors on February 23 presided over by the Chancellor (Viscount Cecil of Chelwood) was marked by a general feeling of regret at the retirement from the Council of Mrs. C. G. Beale (widow of the first Vice-Chancellor) and the resignation of his office as Pro-Chancellor by Sir Gilbert Barling after many years of highly valued service to the University. Mr. Walter Barrow was elected Pro-Chancellor and, after the Chancellor had signified his approval of the election, Sir Gilbert Barling rose from his seat and divested himself of his robes of office saying that these robes, originally worn by the first Vice-Chancellor, had been given to him by Mrs. Beale when he succeeded to the vice-chancellorship. Sir Gilbert now desired, with Mrs. Beale's approval, to present them to the University and he proceeded forthwith to invest with them the new Pro-Chancellor. The Chancellor paid a tribute to Sir Gilbert Barling, whom he described as a man possessed of a great faculty which he could only describe as the faculty of being right. His advice was always to be trusted.

Sir George Kenrick moved a resolution in which the Court gratefully acknowledged the services of the retiring Pro-Chancellor as demonstrator in anatomy in Queen's College in 1885, as professor of pathology in 1886–1893, joint professor of surgery in 1893–1913, dean of the Faculty of Medicine in 1905–1912, member of the Court of Governors since 1900 and of the University Council since 1903, as Vice-Chancellor and chairman of Council in 1913–1927 and Pro-Chancellor from 1927 until the present time. Prof. F. W. Burstall in seconding the resolution paid a tribute on behalf of the academic side of the University. The dean of the Faculty of Medicine (Dr. Stanley Barnes) spoke in very warm and appreciative terms of Sir Gilbert whom he characterised as a great surgeon, a great teacher and a great administrator.

The title of emeritus professor was conferred on Prof. W. S. Boulton (geology and mineralogy) and Prof. J. T. J. Morrison (forensic medicine and toxicology).

CAMBRIDGE.—A University demonstrator in geography will shortly be appointed. The duties will commence on April 1. Particulars can be obtained from Prof. F. Debenham, at the Department of Geography, to whom applications should be sent on or before March 7.

The Balfour studentship in biology has been awarded to F. R. Parrington of Sidney Sussex College.

It has been recommended that the plans prepared by Sir Herbert Baker for the Scott Polar Research Institute be approved.

EDINBURGH.—His Majesty the King in Council has approved of the ordinance providing for the affiliation of the Heriot-Watt College to the University.

Prof. Heinrich Wieland, of the University of Munich, has been invited to give the first Romanes lecture. These lectures are provided from an endowment fund in memory of Dr. Robert Romanes, and James Manners Romanes, brother of the late Miss I. D. Romanes. Part of the endowment is used to bring distinguished chemists from other centres to lecture in Edinburgh.

LONDON.—His Majesty the King, who will be accompanied by the Queen, will lay the foundation stone of the new University buildings on June 26.

The following appointments have recently been made: Prof. J. B. S. Haldane, since 1922 reader in biochemistry in the University of Cambridge and since 1927 head of the Genetical Department at the John Innes Horticultural Institution, to be professor of genetics at University College; Mr. W. P. Yetts, lecturer in Chinese art and archæology at the Courtauld Institute of Art, to be professor at the Institute; Prof. Cyril L. Burt, to the Heath Clark lectureship for 1933.

DUBOIS: The stratigraphic subdivision of the schistogreywacke complex of the Vosges. It is shown that, with or without the middle Devonian, the Visean and especially the lower Visean, holds an important stratigraphical place in the whole of the Vosges. MLLE. S. GILLET: An attempt at a classification of the upper Miocene and of the lower Pliocene of Rumania. The Dacic basin. PAUL FALLOT: Geological observations in the Djebel Kelti massif (Spanish Morocco). J. REPELIN: Observations on the tectonic of the western part of the Nerthe. RAYMOND CIRY: The lateral passage of the Cretaceous with so-called Wealdian facies of the province of Burges to the lower marine Cretaceous of the Cantabric provinces. D. SCHNEEGANS: The presence of the middle Jurassic (Dogger) in the sheet of Ubaye to the north of the valley of Barcelonnette (French Alps). MARCEL THORAL: The existence of the Georgian in the mountains of Lacaune. DAVID STENQUIST. The relation between the daily variations of the earth current and the terrestrial magnetic field. PH. FLAJOLET: The transparency of the atmosphere in the Lyons region. The visibility of the Alps. In a recent note, André Allix, discussing the observations of the visibility of the Alps made at the Observatory of Fourvière, concludes that there has been a progressive obscuring of the atmosphere near Lyons during the last thirty years. These results are now compared with observations at the Saint-Genis-Laval Observatory, made at the same altitude and about 8km. to the south. The two sets of observations are in general agreement, but, in the author's opinion, do not prove a progressive change in either direction. The visibility of the Alps does not appear to be capable of being influenced by the greater or less abundance of smoke. MLLE. MADELEINE FOURCROY: The indirect action of traumatisms on the evolution of the conducting apparatus (in plants). JACQUES MONOD: Demonstrating the axial gradient in the ciliated Infusoria by photolysis by means of the ultra-violet rays. The results entirely confirm those of Child: the ultra-violet rays exert a differential cytological action identical with that of chemical poisons. This shows that the differential susceptibility is not only a question of differences of permeability, but also expresses the fundamental physiological polarity of the cell. V. A. KOSTITZIN: Some quasi-periodic phenomena in closed basins. P. VLÈS: The correlations between the evolution of the weight of infants and the electrical properties manifested at their level. MME. Y. KHOUVINE and G. NITZBERG: The identification and biochemical oxidation of α-glucoheptulite. That α-glucoheptulite is not a mixture has been proved by X-ray photographs. Biochemical oxidation with *Acetobacter xylinum* gave α-glucoheptulose. R. WOLFF and MLLE. LAFRANCAISE: The action of pancreatic extract on glycocine in glycerol solution. J. LIGNIÈRES: The duration of immunity after vaccination against foot and mouth disease.

ROME

Royal National Academy of the Lincei. Communications received during the vacation, 1932. S. CHERUBINO: Classification of hyper-elliptic surfaces from the real point of view. The classification of these surfaces is completed in a manner that appears satisfactory and of useful application. Certain of the more simple and striking relationships between Scorza's nine types (1916) and Lefschetz's seven types (1919) are indicated. B. COLOMBO: An equation with partial derivatives of the fourth order. HANS HAMBURGER: Ribaucour's transformation and spherical representation (3): Ribaucour's cyclic systems. This theory of cyclic systems furnishes other applications of Ribaucour's transformation. On the basis of a deduction made by Bianchi, a formula is derived which determines all the cyclic systems normal to a given surface x (u, v). V. HLAVATÝ: Projective curves of a curve in the projective space P_{n-1} (n = or >3). D. MANGERON: A problem of the contour for a non-linear differential equation to the partial derivatives of the fourth order with double real characteristics. MARIA PASTORI: Properties of conjugated hemi-symmetric tensors. B. SEGRE: Algebraic surfaces having the canonical system combined with an involution. M. PASCAL: The motion of a deformable body which remains similar to itself. (2) Instantaneous centre of velocity and its consequences. F. ZAGAR: The variation of the eccentricity in the problem of two bodies of variable masses. Two particular integrable cases are considered. C. CANNATA: An extension of Woo's formula: intensity of the light diffused by an electron in motion. For the case when the diffusing electron is moving in the same direction as the incident pencil, Woo has calculated the intensity of the diffused radiation on the basis of classical theory. Woo's result is now confirmed by an analogous but simpler method, and is extended to the case when the electron is moving in any direction whatever. C. DEI: Circuits with a capacity in parallel on a diode in saturation. A. FERRARI and G. TRAMPETTI: Investigations on the behaviour of mixtures of zinc oxide and anhydrous zinc chloride at high temperature. The solubility of zinc oxide in fused zinc chloride does not exceed 5 per cent (molecular). The existence of anhydrous zinc oxychlorides appears improbable, the hydrated oxychlorides undergoing decomposition in the fused mixture. C. GUARESCHI: First results of the combined method: differential susceptibility and vital colours, in the development of Amphibia. T. PERRI: Transplantation experiments with Amphibia. G. AMANTEA and V. FAMIANI: Further considerations on the possibility of obtaining permanent beriberi phenomena by exclusion of the *B* factor. The results previously obtained with pigeons have now been confirmed by similar experiments on hens. V. FAMIANI: (1) The capacity for food consumption after fasting. When pigeons which have fasted until they have lost 20 per cent in weight are fed, they are at first able to take only very little food, but the amount taken gradually increases to about double the normal quantity, at which it persists until, or even after, the original body-weight has been resumed. (2) Reconstructive food value of the embryos of various cereal and leguminous seeds. These embryos are not only of greater value than other parts of the seeds in normal nutrition, but also they result in more rapid resumption of weight when administered to fasting pigeons. G. MEZZADROLI and A. AMATI: Action of certain alkaloids on the development of *Aspergillus niger*. Quinine and strychnine, in small concentrations, favour the growth of this mould, but caffeine exerts an inhibiting influence. A. SALVATORI: Contribution to the knowledge of the nature and value of Bezssonoff's reaction for the *C* factor. Bezssonoff's reagent is not specific for the *C* factor, but merely reveals the presence, in all antiscorbutic materials, of a reducing factor.

Forthcoming Events

Monday, March 6

VICTORIA INSTITUTE, at 4.30—(in Committee Room B, Central Hall, Westminster).—Dr. J. Burnett Rae: "Psychology and the Problem of Inadequacy" (Dr. A. T. Schofield Memorial Paper).

UNIVERSITY OF LEEDS, at 5.15.—Prof. A. C. Chibnall: "The Biochemistry of Plant Waxes".

ROYAL SOCIETY OF ARTS, at 8—(Cantor Lectures).—Arthur Stephenson: "Welding and Allied Processes for Engineering Purposes" (succeeding lectures on March 13 and 20).

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Sir Douglas Mawson: "Kerguelen".

Thursday, March 9

CHEMICAL SOCIETY, at 7—(extra meeting at the University of Manchester).—Prof. E. K. Rideal: "How Chemical Reactions Go".

CHADWICK PUBLIC LECTURE, at 8—(at the Royal Sanitary Institute).—Dr. E. Killick Millard: "Housing".

Friday, March 10

ROYAL INSTITUTION, at 9.—Lord Rutherford: "Recent Researches on Transmutation of the Elements".

INSTITUTE OF METALS, March 8–9.—Annual General Meeting.

Power Alcohol

THE motor-car, of which there are so many millions, has provided a market as never before for a variety of manufactured products, and above all for the fuel used to drive its engine. It is responsible for the development of the great oil industry, including such highly technical sections of it as refining and cracking. The fact that only some favoured territories contain oil has introduced a new factor into the balance of international trade, resulting, for example, in large purchases of oil by British and European countries from the United States. Had world conditions remained what is termed normal, there would have been no desire to do other than buy oil of satisfactory quality at the cheapest delivered price, irrespective of its origin, but as a consequence of the dislocation of exchanges and the parlous condition of agriculture, the provision of substitutes for imported oil is being considered in a number of countries. Most of these alternatives would scarcely stand the test of scientific economics in normal times, a fact which necessitates their adoption under some form of government protection or compulsion, but it is none the less probable that, once established, a series of conditions might be set up which would favour and justify their continuation. At all events, the stimulus to invention and experiment, with the object of replacing imported oil by some other fuel, is present in all non-oil producing countries.

Petrol may be produced by the hydrogenation of coal or of low-temperature tar derived from coal and, as is well known, considerable quantities have been manufactured in this way in Germany, though it is not yet claimed that the process is a complete success, either economically or technically. A similar hydrogenation project, involving a capital expenditure of £7,000,000, has recently been the subject of controversial discussion in Great Britain: in particular, it is impossible to embark on it without a guarantee of the continuation of the present tax on petrol for a number of years, as the cost at the factory of synthetic petrol from coal is very materially greater than the price at a port of the imported article.

A car may be propelled by means of ordinary towns' gas, compressed for the purpose in cylinders, and the trials already made in this direction have shown that so far as the power obtained and the cost of the gas per mile run, the possibilities are great. The major problem is in connexion with the recharging of the cylinders and the guarantee against accident in usage. Parallel studies are being made with hydrogen gas in cylinders, the gas being generated cheaply at electric power stations during the off-peak load period.

It is, however, primarily to another liquid fuel, the production of which has a great bearing on agriculture, that we wish now particularly to refer, namely, alcohol. This is already in use in a number of countries, and it may well be that the necessity not to buy from America, which is being forced on Europe by its inability to obtain dollars, will lead to a very large development of the use of power alcohol in the near future.

It may surprise those who judge the cost of alcohol by the retail price of potable spirits that it should ever be competitive with petrol: spirits, however, are made from expensive raw materials, are maturated for seven years or longer, are sold in bottles, and carry heavy transport, selling and advertising charges, to say nothing of the excise taxation, which in itself makes up the greater bulk of their cost. Industrial alcohol to-day is made in large, highly organised factories by fermentation of the cheapest possible carbohydrate material, in particular black strap molasses, which is transported from its place of origin in tank steamers and stored in large tanks. It is pumped and handled just like oil, at a minimum cost to the user. The alcohol produced is separated from the fermentation mash in a continuous still with a minimum expenditure of steam, and can be concentrated in one continuous operation to an anhydrous product containing 99·99 per cent of alcohol, which is quite a different material from the 96 per cent spirit of a year or so ago.

It is the new method for the production of absolute alcohol which has made the advent of power alcohol certain. It is based on the well-known work of Prof. Sydney Young, namely, that a ternary mixture of three liquids will boil at a lower temperature than any one of them singly, or any mixture of two of them. Young's laboratory results have had to wait nearly thirty years for their full application to practice. Yet another example is afforded by them of the ultimate value to industry of results which were seemingly at first only of theoretical interest. It is possible and practicable to add to an aqueous alcohol a third liquid, such as benzene or, preferably, benzene with a little high-boiling petrol from a particular fraction, and drive off all the water as a ternary mixture, leaving dry or absolute alcohol behind at the lower plates of the still. The ternary mixture, when condensed, separates into two layers, the aqueous being rejected after recovery of such alcohol as it retains and the benzene being returned to the circuit. The distillation plant for this purpose appears somewhat elaborate at first sight, but when once it has been tuned up it operates with great certainty and economy. Prior to its perfection the strongest alcohol which could be obtained by distillation was of 96 per cent alcohol, and further dehydration could only be effected by means of anhydrous solids, an operation which was far too costly for the purpose in view.

The necessity for dry alcohol to mix with petrol is occasioned by the fact that in presence of more than a minimum quantity of water the mixture separates into two layers, particularly below certain temperatures. The highest proportion of absolute alcohol that can be added without requiring carburettor or engine adjustment is 15 per cent. This proportion actually gives a better fuel than with petrol alone, although the calorific value of alcohol is less than that of petrol. Ample practical tests in all countries have served to confirm the utility of alcohol as a motor fuel: it is common practice to use a proportion of it in racing cars in Great Britain. This is not the place to discuss the cost of absolute alcohol on the large scale, but there is no doubt that, suitably denatured and free from excise charges, it could be added to petrol bearing the present excise duty in Britain without materially increasing the cost, and the same applies elsewhere.

Alcohol will mix in all proportions with benzole—the home produced spirit from our gas works and coke ovens: exhaustive, and on the whole satisfactory, tests were made by the London General Omnibus Company some years ago with such fuels. The use of mixtures containing alcohol, benzole, and a third component has been tried with some success. In Germany the latest attempt at a 'home' motor spirit is to use a mixture having the percentage composition of absolute alcohol, 10; synthetic methanol, 10, made from water gas; benzole, 10, from the coke ovens; petrol, 35, made by hydrogenation of coal oil; and imported petrol, 35. Of this mixture only one-third would be imported from foreign sources, the rest being the domestic product of German agriculture, the chemical and the coke oven industries. The outcome of the experiment with so complex a fuel will be watched with considerable interest. Previously German law had required a minimum proportion of alcohol in all petrol used, which quantity had more or less equalled the capacity of the dehydrating plants a year ago. In Germany about two-thirds of the alcohol is made from potatoes, the rest coming from molasses, grain and paper pulp liquors.

France was the first country to introduce legislation making the purchase of alcohol by the oil companies compulsory. The bulk of the alcohol is used by the Paris omnibuses in the form of a 50 : 50 mixture of alcohol and petrol, the engines being specially adjusted for the purpose: such a fuel does not lend itself for general use. In France at present the conditions are not too favourable for the extension of the absolute alcohol industry, owing to the high cost of the carbohydrate material and the location and size of the distilleries, but political influences might very readily change the whole position.

In Sweden some 6 or 7 million gallons of alcohol are produced each year from the residues of the paper factories, all of which is sold in a 75 petrol : 25 alcohol mixture.

There is no need to enumerate what is being done in many other countries: in the British Empire, a mixture 'Shellkol' is marketed in Queensland. Enough has been said to indicate that, in those countries which have no petroleum supply, the study of domestic substitutes for it has become a major problem, both of economics and defence, and that in many countries national programmes are in hand to manufacture and dehydrate it in quantity. In those lands where carbohydrates can be grown cheaply and abundantly, the advantages to be derived from the use of alcohol lie in a market for surplus agricultural products. In South Africa, for example, the potentialities of cheap alcohol production are very great.

It is less than ten years since absolute alcohol was a laboratory rather than a commercial product. Its manufacture by the benzene-azeotropic process, for which the credit must be given to French enterprise, though the theory of the reaction was of English origin, has brought the world-wide utilisation of power alcohol definitely nearer now that the danger of the presence of water can be eliminated from the alcohol-petrol mixture.

If we look at the subject of international trading from the broader point of view, we are faced with the fact that at the moment many of the latest developments of modern civilisation are in danger of becoming useless. Of what value is the highly organised system of transporting materials from one country to another by land or by sea if trading be rendered impossible by lack of a medium of exchange? Even if one country, rich in a particular natural resource, is able and willing to supply the world, other countries are being forced to provide substitutes of their own, more or less adequate, never entirely justified from the point of view of world economy. In the individual countries the resources of science are being used as never before to develop these alternatives. More than ever do we need the help of science in planning the campaign of our activities, "the era of conscious and deliberate management". Are we, for example, to buy less imported petrol? Do we wish to encourage agriculture? Such are among the questions to be answered. If the reply is in the affirmative, then a plan must be prepared to be operative over a period of years, such as has been operative for beet sugar; a plan which can only be drawn by scientific experts in collaboration with the politicians, and can never be drafted by lawyers in the form of an Act of Parliament.

These anxious times demand new remedies, amongst them perhaps a body scientific which is articulate, a council of science putting on record the ascertainable facts on the broad economic questions, acting as a planning department for the best utilisation of the materials and men of the nation.

Intensive Natural History

The Natural History of Wicken Fen. Edited by Prof. J. Stanley Gardiner. Part 6. Pp. 489–652 + xii. (Cambridge: Bowes and Bowes, 1932.) 7*s.* 6*d.* net.

THE name of Wicken Fen in Cambridgeshire has long been associated in the minds of field naturalists with the flora and fauna that was probably characteristic of the whole of the 'Great Level' prior to its drainage in the seventeenth century.

Interesting to the botanist as the home of *Liparis lœselii*, *Viola stagnina*, *Cladium mariscus*, *Lathyrus palustris* and a number of other rare or local species, Wicken Fen has equal attractions for the zoologist as a locality for the very rare water beetle *Hydrochus carinatus*, the swallow-tail butterfly and many other interesting animals. Unfortunately the changes, initiated by the artificial drainage of the past, still continue and no less than six of the Lepidoptera formerly characteristic of Wicken, including the large copper (*Ocneria dispar*) and a moth, *Lælia cœnosa*, are no longer to be found there. So too with the flora, *Senecio paludosus* and *Typha minima* would both appear to have become extinct. Such changes in the past suggest an especial suitability in this area as the subject of intensive study, particularly with regard to the fluctuations in frequency, which plants and animals alike exhibit, and respecting the underlying causal factors of which we are so ignorant. These fluctuations are well illustrated at Wicken by the moth *Hydriomena sagittata* which has twice, within recent years, been apparently so scarce that it was feared to be on the verge of extinction.

This volume illustrates the great value of intensive study of a limited area, a value which will be enhanced in the future as the study of the plant and animal ecology of the area progress side by side. It is an outcome of such intensive work in a single locality that Wicken Fen has yielded four spiders which, so far as is known, are endemic, and two or three more which are known only from this locality in Britain. Nineteen ichneumon flies are here recorded by G. L. R. Hancock from Wicken as the first British records and the earthworm, *Allobophora icenorum*, described by Miss Pickford is another species new to science. It is indeed not too much to say that if the same amount of money, time and energy had been devoted in the past to intensive studies at home that has been spent on foreign expeditions, the yield to science would probably have been far greater.

It is not merely in the addition of new species, however interesting, that the value of intensive studies lies but also in the many fundamental problems upon which light is shed. It is true that the preliminary results, presented here in the fifty-six articles by a number of different authors, show little evidence of co-ordinated effort between the various branches, but such correlation will doubtless develop as the work proceeds, when such relations as may exist between the distribution of the animal population and the phases of the plant succession with their respective partial habitats, may be brought to light. In the meantime, these pages contain a large amount of information on the most diverse topics from the soil Protozoa and Collembola to the fossil vertebrates, the history of the drainage of the 'Great Level' and a comparison of the Fen of to-day with that of fifty years ago. These cannot fail to interest the biologist whatever may be his special field of interest.

The late Prof. Yapp laid a valuable foundation for future work in his account of the structure of fen vegetation from the static point of view, whilst Godwin and Tansley here develop the dynamic aspect as presented in the fen successions of which, in addition to the familiar primary succession passing from reed-swamp through 'carr' to deciduous woodland, there are recognised several 'deflected' successions consequent upon the interference of man. Data respecting the changes in level of the soil water show that the water table is slightly convex in winter and in summer concave owing to the high rate of transpiration, whilst the normally alkaline soil water contains only a small amount of dissolved oxygen and a high content of carbon dioxide.

To the concept of fenland conditions thus established future work can be related. Most of the work so far accomplished has aimed at the by no means easy task of listing the species of the area and, where possible, obtaining some measure of their relative and absolute abundance. Of vascular plants, Wicken provides less than two hundred species; but the magnitude of the work involved in a more qualitative list of the insect fauna can be realised from the fact that the Staphylinidæ alone comprise nearly two hundred and seventy species.

A perusal of these pages cannot fail to make the reader feel a debt of gratitude to those responsible for obtaining this area for the National Trust and to Prof. Stanley Gardiner for having initiated its intensive study on modern lines.

E. J. SALISBURY.

Oceanography

Bulletin of the National Research Council. No. 85: Physics of the Earth—5: Oceanography. Prepared under the auspices of the Subsidiary Committee on Oceanography. Pp. v + 581. (Washington, D.C.: National Academy of Sciences, 1932.) 5 dollars.

SUMMARIES in any branch of science are always of value to the specialist and general reader alike. In oceanography, where so much of the work is of a highly technical nature, the need is great for a practical textbook giving not only a general survey of this vast and varied field, but also assisting towards a better knowledge of the newer and more specialised sections of research.

We think the present volume adequately fulfils such a function.

The work is a composite effort by a number of separate authors, each chapter being contributed by a specialist. The result is, in most cases, a lucid and up-to-date account of each particular theme, such as would be difficult or impossible for anyone but a specialist to produce. In nearly every case, a satisfactory bibliography is included. The chapters are of varying merit, strikingly dissimilar in method of treatment and style; at least one section has been expanded unnecessarily and occasionally considerable repetition occurs. All these are the obvious and more or less inevitable results of the composite method of production.

In the first section of the book, Littlehales gives a concise and lucid summary of the present state of our knowledge of the configuration of the ocean bottom and includes definitions of the terms used in its description. Then Collet classifies bottom deposits from physical, chemical and biological points of view, but it is to be regretted that he does not add a bibliography.

"Properties of Sea Water" is the next section and in our opinion the best. Here Prof. Thomas G. Thompson deals with the physical properties in detail, and in association with Robinson provides an admirable treatise on "The Chemistry of the Sea". Some space is devoted to descriptions of the more usual types of water samplers, the rest to a discussion of the substances found in ocean water, even those present in minute traces. The accounts of carbon dioxide equilibrium and of the physical chemistry of oceanic salt deposition (Igelsrud) are of great interest.

In the "Movements of the Sea" are considered waves, tides and currents, dynamic oceanography, ocean circulation and ice in the sea. With perhaps the exception of "Dynamic Oceanography", the subjects are treated on orthodox lines. The next section, devoted to oceanographical instruments and methods, is largely confined to a consideration of the apparatus used on the last cruise of the *Carnegie*. The most interesting portion is the short chapter by Iselin on bottom samplers. Unfortunately, no consideration is given to biological equipment as such.

The book concludes with a consideration of the "Interrelations of Oceanography" under the separate heads of meteorology (C. F. Brooks), biology (A. G. Huntsman) and geology (C. Schuchert). While quite interesting, some portions at least could have been shortened with profit.

The volume covers a large field in an astonishingly efficient manner; and while full of technical and highly specialised information, should provide interesting reading even for those with but a casual interest in this branch of science.

E. F. T.

Tribes of the Southern Sudan

Pagan Tribes of the Nilotic Sudan. By Prof. C. G. Seligman and Brenda Z. Seligman. (The Ethnology of Africa, edited by J. H. Driberg and Dr. I. Schapera.) Pp. xxiv + 565 + 61 plates. (London: George Routledge and Sons, Ltd., 1932.) 42*s*. net.

THIS book is the second to be published in a series of works on the ethnology of Africa edited by Mr. J. H. Driberg and Dr. I. Schapera. In his introduction to the book, Sir Harold MacMichael, Civil Secretary to the Sudan Government, points out that though a good deal has been written at one time or another concerning various tribes inhabiting the southern Sudan, the information has been somewhat fragmentary and not always reliable; and accordingly Prof. and Mrs. Seligman's work being, as it is, a general conspectus of the people, their traditions, their culture and ways of thought, cannot fail to be of great practical value to their fellow workers and to the administration of the Sudan.

Much of the introduction might be quoted to show the value of anthropological research as applied to the business of administration, and an authoritative statement, coming as it does from so able and distinguished a public servant as Sir Harold MacMichael, is all the more welcome. The Sudan Government has always taken interest in and given help in a practical way to ethnological investigation, an example which our Colonial Office has been slow to imitate, and which might have saved some blundering.

When working with so many different tribes, the question of an orthography must always present difficulties, and the authors are much to be congratulated on having worked out a suitable compromise, though I should have preferred to have seen *Lugbware* modernised further to its recognised form *Lugbwara*.

I like the schema of Nilotic and Nilo-Hamitic migration on p. 19, and think it will be more generally accepted than some which have been published; though at the same time, I should prefer to reserve judgment on the placing of the Lendu in the same group with the Lugbwara

(p. 463); there may be affinities in language, but physically they seemed to me to be of a different race altogether.

I was interested to see the account given by Mr. R. Gunnis of Olia's rain-stones (p. 131), because I was present when this took place, but I do not remember the incident of the breaking of the mud floor; the impression I hold was that the stones were in a pot buried in the floor, the top of the pot being flush with the floor. The stones were similar to those I had seen at Shindiro. Olia was somewhat of a puzzle; he reckoned himself as being pure Acholi, but he had some bits of things which he said had been given to his ancestors when they had visited the Mukama of Bunyoro; he had these rain-stones, and he lived next the Madi. I have always understood that the Madi crossed the Nile below Nimule about sixty years ago, after a famine, and lived on land formerly in occupation of the Acholi. At Atiak some intermarriage had taken place, and Olia's followers were not all pure Acholi, and had indeed adopted some Madi customs.

Now one of the most interesting points brought out by Rogers in his account of the Madi rain-stones (*Man*, 27, 58; 1927) is the number of chiefs who had these stones, twenty-two in a population of about eight thousand adult males, which looks very much as if each territorial chief tried to obtain the ascendency over his fellows by becoming a rain chief, for that area is subject to periodical food shortages. Is it not possible that Olia's forbears took a similar course, for his country is also in a dry zone? This is only speculation, founded on impressions rather than facts, because one has to remember that the southern Acholi do not ordinarily have rain-makers. That the Acholi of the southern Sudan also have rain-makers seems to me only to show what we know to be true, that they are of mixed origin. The point now is to determine how long it is since the chief of Atiak set himself up to be a rain-chief, or, alternatively, is he of such pure Acholi stock as he is usually represented to be?

The authors have been set an almost impossible task, that of bringing within the covers of a single book an account of all the tribes of the southern Sudan, tribes of widely different cultures, and some about whom we know very little. It is apparent also that they have found considerable difficulty in reconciling observations made by different investigators. That they have succeeded as well as they have done is a matter of great credit to them, and one feels that though there must of necessity be gaps in the picture they have drawn of the life of any one particular tribe, such gaps may be filled in by the administrator or missionary who is working in that tribe from knowledge gained in his own experience.

The book is well illustrated, and though one may grumble at the price, one cannot get away from the fact that here there is, in convenient form, all that is now known on certain aspects of native life in the southern Sudan, and the very incompleteness of our knowledge may stimulate others to investigate and publish matter which will give us the full story. E. B. HADDON.

Short Reviews

Festivals and Songs of Ancient China. By Prof. Marcel Granet. Translated from the French by Dr. E. D. Edwards. (The Broadway Oriental Library.) Pp. ix + 281. (London: George Routledge and Sons, Ltd., 1932.) 18*s.* net.

THE English version of Prof. Granet's study and interpretation of certain odes of the Chinese classic, the "Shih Ching", is addressed to a wider public than the sinologue and differs from the French edition in the omission of the original texts and the Chinese characters in the notes. Scholars may regret it; but if, as the translator hints, this has made possible the production of Prof. Granet's remarkably penetrating analysis of the poems in a form more accessible than that of the original edition, it is a gain rather than a loss.

For the benefit of those who have not had the advantage of knowing the work in its original form, it may be said that the author takes certain of the love poems of the "Book of Odes" and, setting aside the symbolic and archæological interpretations of the Chinese commentators, regards them as survivals of what were once genuine expressions of an emotion. Analysing them from this point of view, he infers that they are parts of a forgotten socio-religious seasonal ritual of a primitive rustic organism—a village festival which served to reaffirm the social bond by affording an opportunity for the meeting of family or local groups and of members of the two sexes, isolated at other times of the year. These songs were, he holds, the material of an antiphonal contest between the sexes which culminated in betrothal and marriage. Prof. Granet quotes extracts from the records of travellers in the Far East which lend support to this original view.

Needless to say, nothing of this appears in the Chinese commentaries. Their interpretations, however, which are given, are not without significance, in spite of their divergence from Prof. Granet's purpose. As an example of Chinese literary canons and symbolism they illuminate the psychology of a remarkable literary tradition.

Bauxite and Aluminous Laterite: a Treatise discussing in Detail the Origin, Constitution, known Occurrences and Commercial Uses of Bauxite. By Dr. Cyril S. Fox. Second edition, partly rewritten and enlarged. Pp. xxxi + 312. (London: Crosby Lockwood and Son, 1932.) 30*s*. net.

IN the interval since the publication of the first edition of Dr. Fox's book (noticed in NATURE, 120, 800; 1927), a feature of the bauxite industry has been the increased production from southern Europe, in particular from Hungary and Yugoslavia. Most of the new matter in the second edition results from a visit by the author, in company with local geologists and mining engineers, to the deposits of Austria, Hungary, Italy and Yugoslavia. The exact mode of origin of the important European deposits has always been a matter of some uncertainty, and linguistic difficulties have tended to hamper British geologists in the study of the literature of these deposits. New information on this subject is therefore welcome.

The author's observations, and those of local geologists, have led him to put forward the view that the so-called Mediterranean or *terra rossa* type of bauxite is not a residual deposit, but a true sediment, laid down in water. He still thinks it very probable, however, that both true *terra rossa* and the bauxite of the limestone regions of southern Europe are derived from a common origin—the impurities of the limestones.

The new matter is incorporated in an introduction and a supplementary chapter. An important omission from the bibliography, which has not been brought up to date, is de Lapparent's recent memoir, "Les Bauxites de la France méridionale." (*Mém. de la Carte géol. de la France*, 1930.) Statistical information, which can be obtained from current government publications, is omitted from this edition. Otherwise the book is little changed.

V. A. E.

Proverbes et maximes Peuls et Toucouleurs traduits, expliqués et annotés. Par Henri Gaden. (Université de Paris: Travaux et mémoires de l'Institut d'Ethnologie, Tome 16.) Pp. xxxiii + 368. (Paris: Institut d'Ethnologie, 1931.) 56.25 francs.

M. HENRI GADEN'S collection of proverbs comes mainly, but not exclusively, from peoples encountered at St. Louis in French West Africa. The author has classified them under various headings, such as personal relations and the family, authority, good and evil, courage and intelligence, goodwill and avarice, life in general, practical wisdom, respect for tradition and the like. He has wisely added explanations and annotations freely; for many of the proverbs belong to the category specifically recognised by the people themselves, in which by allusion the meaning is shown to be quite other than that conveyed ostensibly by the words employed. Another and frequently recurring type belongs to the class which conveys a moral. Allusions to magical belief are common and can usually be shown to lie behind the proverbs which express distrust or dislike of neighbours. The occurrence of a succession of premature deaths among children or live stock in a house, for example, will be attributed to the proximity of a sorcerer as a neighbour, who, by the force of his nature, is compelled to seize upon the *bâlu*, the 'shadow' or 'image' of his victim, especially when it leaves the body during sleep.

M. Gaden prefaces his collection by an introduction dealing with language and vocabulary, and has added a very full and useful index of all the vernacular key words which occur in the proverbs.

Electricity and Magnetism for Beginners. By W. C. Badcock and Dr. E. J. Holmyard. (Dent's Modern Science Series.) Pp. viii + 199 + 8 plates. (London and Toronto: J. M. Dent and Sons, Ltd., 1931.) 2*s*. 6*d*.

THIS is a very welcome addition to the growing number of books written in what we may venture to call the good modern style; that is, not just a descriptive catalogue of marvels, or a collection of things to do made to appear of educative value by the free use of all the latest terms, though the background essential to their understanding is entirely lacking; but a really clear survey of the subject bringing out the fundamental principles, without a comprehension of which no real progress can be made, and written in an easy conversational mode, interesting historical references and practical applications falling naturally into place in the coherent story.

There is, however, we suggest, one very real danger in this sort of thing, particularly when done as well as it is in the present case: the book is not, indeed as the authors say, could not be, mathematical; but so comprehensive is its range and so lucid the qualitative explanation of the varied phenomena dealt with, that when the time comes for the more complete quantitative treatment the pupil may find the 'gilt all off the gingerbread', and his interest suffer accordingly.

Elastic Energy Theory. By Prof. J. A. van den Broek. Pp. x + 260. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 22*s*. 6*d*. net.

VARIOUS methods are at hand for the analysis of statically indeterminate structures. The author, feeling that the elastic energy theory is inadequately treated in British or American textbooks dealing with strength of materials, has developed the theory systematically and has applied it to a wide range of redundant frames and beams.

A. F.

The Scientific Work of Joseph Priestley

By PROF. J. R. PARTINGTON, M.B.E.

PRIESTLEY'S most important scientific work was the result of a further development of the experimental technique available in his day for the manipulation of gases. This led him to the discovery of a number of new gases, and the creation of a special branch of chemistry called in the older books "Pneumatic Chemistry". The ascertained facts enabled Lavoisier to make such changes in the theory of chemistry that he may fairly be called the founder of the science as we know it to-day.

The existence of gases with characteristic properties was known before Priestley's time. Van Helmont, about 1620, had recognised the existence of at least two gases different from air, gas sylvestre (carbon dioxide) and gas pingue (hydrogen or hydrocarbons), and had invented the name gas, derived from chaos, which Priestley did not use. Van Helmont did not succeed in collecting gases; when the materials generating a gas, a process previously called "intestine fermentation", were sealed up in a glass vessel, the latter was "filled with plentiful exhalation (yet an invisible one) and however it may be feigned to be stronger than iron, yet it straightway dangerously leapeth asunder into broken pieces".

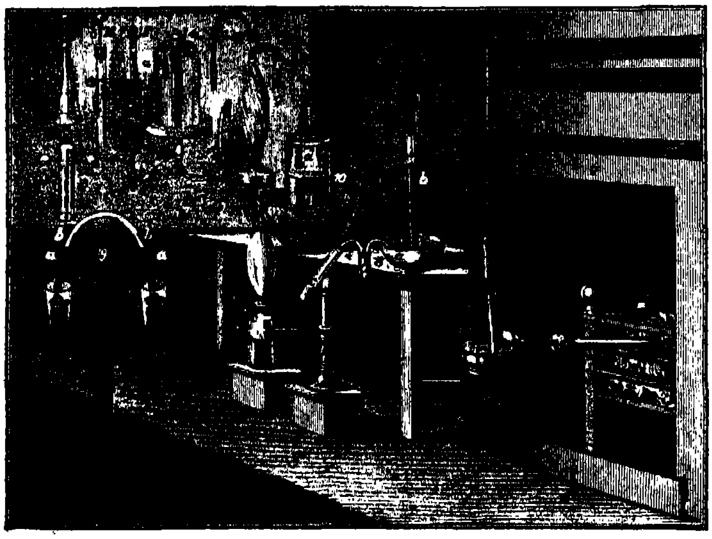

FIG. 1. Part of Priestley's Laboratory. From "Experiments and Observations on Different Kinds of Air".

Hydrogen was first collected from iron nails and dilute acid in an inverted bottle by Boyle: "the cavity of the glass was possessed by the air, since by its spring it was able to hinder the liquor from regaining its former place". Boyle also showed that hydrogen was combustible and would not burn without air. A little further progress in the manipulation of gases was made by Mayow (1674), and Stephen Hales ("Vegetable Staticks", 1727) collected over water in an inverted globe the "air" given off when all kinds of substances, such as saltpetre and coal, were heated in a gun barrel, or when sulphuric and nitric acids acted on metals. Hales measured these airs and then apparently threw them away without examining their chemical properties, regarding them all as modified air. His severely quantitative technique seems to have been influenced by the writings of Newton who, as Priestley says, "as he had very little knowledge of air, so he had few doubts concerning it". Cavendish in 1766 collected fixed air (carbon dioxide), discovered by Black in 1754, over water and mercury, and carefully investigated its properties, as well as those of inflammable air (hydrogen), discovered by Boyle. He used drying tubes and determined the densities and the solubilities of the gases in water and alcohol. The first use of mercury for collecting soluble gases is incorrectly attributed by Kopp to Priestley.

Cavendish's pneumatic trough had no shelf, a fitting introduced in a crude form by William Brownrigg, of Whitehaven, whose paper appeared in 1765, although it had been communicated to the Royal Society twenty-four years previously and was known to Hales and probably to Cavendish. Scheele, who used very simple apparatus and collected the gases in bladders (as did Cavendish) as well as jars, carried out his investigations from 1770 to 1772 (or 1773), but the work was not published until 1777, so that Priestley's discovery of oxygen in 1774 was made independently of Scheele's work.

Priestley's researches on gases were initiated by a chance event. In 1768 he lived at Leeds near what he calls a public brewery, and began to make experiments on the fixed air, "of which there is always a large body ready formed, upon the surface of the fermenting liquor". He showed that it could be absorbed by water to make an artificial Pyrmont water, and devised an apparatus for producing it from chalk and oil of vitriol, his supply at the brewery having been cut short by an unfortunate experiment in which a vat of beer was spoiled. He thought the reason for the turbidity produced in lime water by air in which a candle had burnt out was that "flame disposes the common air to deposit the fixed air it contains", an inability to furnish a correct explanation for a good experiment which is typical of his work from first to last.

Priestley took as his guide in chemical experiments a theory which he found exclusively professed by the chemists of his day, that reversion to the conceptions of Plato and Aristotle called the theory of phlogiston. He has been reproached for his use of this theory, but clearly unjustly, since the theory was as inextricably entangled in the scientific thought of the eighteenth century as that of the ether a century later or the electron to-day. Macquer, writing in 1778, refers to it as "the surest guide we can take in chemical experiments"; Fourcroy continued to teach it until 1786–87 and Berthollet until 1785. Cavendish, a man of the highest intellectual capacity, believed in it, so far as we know, until his death in 1810, and Priestley still defended it in his last work, "The Doctrine of Phlogiston Established", in 1800 and 1803. It persisted in Germany after this. It is too much to expect a Laocoon to throw off such coils; a Hercules such as Lavoisier was necessary.

The researches on gases carried out by Priestley are collected in six volumes of "Experiments and Observations on Different Kinds of Air" (1774–86; abridged in three volumes, 1790; a modern abridgement in one volume for the use of students is much to be desired). Its title is correct, and the work itself reveals clearly the progress made by the mind and hands of the great experimenter. The results are given in the order in which they were found, as in Faraday's publications, and the apparent lack of order, systematisation and condensation, which intrudes on the attention of a hurried reader, is responsible for the incorrect judgment of the historians of chemistry, that Priestley was a hasty and careless worker. He certainly left too many experiments unfinished and failed to follow up many interesting results. His range of tests was too restricted, a lighted candle and a living mouse being his favourite 'reagents'.

Priestley's apparatus was simple, being, as he says, "nothing more than the apparatus of Dr. Hales, Dr. Brownrigg and Mr. Cavendish, diversified and made a little more simple". He worked in the midst of his family and Fig. 1 shows his laboratory. A substance is being heated in a gun barrel in the fire, the evolved gas being collected in a suspended pneumatic trough over mercury. A substance in the tube 8 *c* is heated by a candle and the gas, after passing through a trap *d* to separate any liquid carried over, is collected over mercury in 8 *b*. In 10, a gas evolved in the bottle *c* is collected over water, passing through a bladder on the way so as to allow of the bottle being agitated, rubber tubing being then unknown. Some apparatus is shown on the chart at the back, and 19 is a piece of apparatus for passing electric sparks through a gas, as used by Cavendish.

The pneumatic trough, which is in its modern form, and auxiliary apparatus, are shown in Fig. 2. The trough, which is provided with a fixed shelf, contains water. The jars *c*, *f* and *d* stand on the shelf *bb*, the jar *c* receiving gas from the bottle *e* fitted with a bent glass delivery tube. In the inverted glass *d* is a mouse, these animals being kept in the arrangement 3. The jar *f* contains a cup supported on a wire stand, also shown in 5; in the cup a substance may be exposed to the gas and if necessary heated by a burning glass. A plant is shown growing in the gas jar 2, and other small pieces of apparatus may be seen. The mice used were kept on "a shelf over the kitchen fireplace where, as is usual in Yorkshire, the fire never goes out". They live, he found, entirely without water and when passed through water "they require and will bear a very considerable degree of heat to warm and dry them".

With such apparatus Priestley investigated the properties of fixed air and inflammable air, discovered three gaseous oxides of nitrogen, ammonia gas (alkaline air), hydrogen chloride (acid air), sulphur dioxide (vitriolic acid air) and silicon fluoride (fluor acid air). The experiments on the oxides of nitrogen are particularly detailed and interesting.

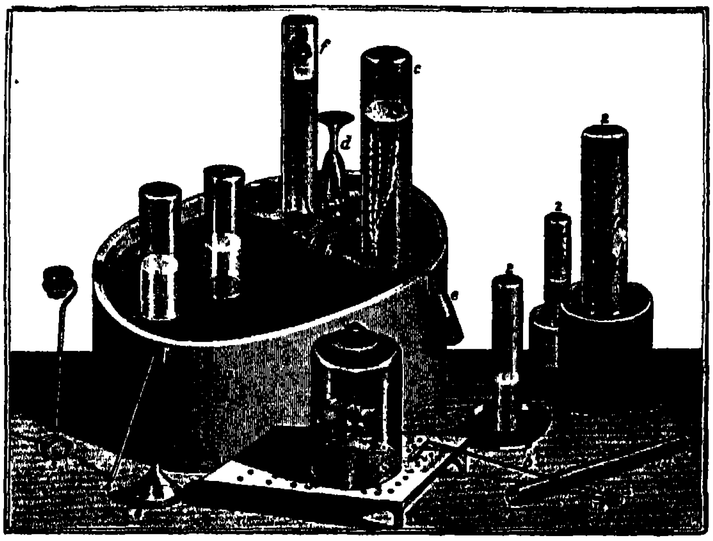

FIG. 2. Pneumatic trough and other apparatus. From "Experiments and Observations on Different Kinds of Air".

The discovery of oxygen on August 1, 1774, in the house of his patron, Lord Shelburne, falls somewhat apart from the rest of Priestley's investigations on gases. It was rather a chance discovery, the result of an experiment performed without definite purpose, as though "more is owing to what we call chance, that is, philosophically speaking, to the observation of events arising from unknown causes, than to any proper design or preconceived theory in this business". Among other materials heated in small tubes over mercury by means of a large burning glass was red precipitate of mercury, from which a gas was evolved in which a candle "burned with a remarkably vigorous flame . . . I was utterly at a loss how to account for it". After the candle came the mouse, and after the mouse Priestley himself. He found that the new air was respirable: "who can tell but that, in time, this pure air may become a fashionable article of luxury. Hitherto only two mice and myself have had the privilege of breathing it". He suggested the use of oxygen in cases of pneumonia, and in the production of high temperatures.

Priestley believed in rapid publication, as did Faraday: "a person who means to serve the cause of science effectually, must hazard his own reputation so far as to risk mistakes in things of less moment", and all his results were available without delay to others, who could make better use of them than he could himself.

In August 1771 Priestley had found that vegetation, such as growing mint, spinach and groundsel, restores air vitiated by burning candles or by the breathing of animals: "the injury which is continually done to the atmosphere by the respiration of such a large number of animals . . . is, in part at least, repaired by the vegetable creation". In 1778 he found that water plants growing in water containing fixed air evolve oxygen. The part played by light in the process of photosynthesis, although known to Priestley, was more fully worked out by Ingen-Houss in 1779.

Another "random experiment", made in 1781, in which moisture was found to result from the explosion of a mixture of common air and inflammable air, led to Cavendish's research on the formation of water from hydrogen and oxygen. In Priestley's own extension of this work, considerable confusion and error resulted from his neglect to distinguish clearly between hydrogen and other combustible gases, such as carbon monoxide and hydrocarbons. This confusion remained until about 1800, when Cruickshank, of Woolwich, cleared up the matter.

Neither Priestley nor Cavendish was able to draw correct conclusions from his experiments. This was reserved for Lavoisier, "a great architect, who laboured little in the quarry" in the obscurity of which the two experimenters worked. Priestley never professed to be a chemist, and in the full sense of the word never was. His range of knowledge was too restricted, and he was thus incapable of appreciating the correct interpretations of his experiments when they were clearly placed before him.

Priestley's mind was powerful and broad: he was a good classical, oriental and modern linguist, who was able to argue points of theology with more orthodox divines with the scriptures in the original languages. He also had read extensively in philosophy and theology, and became involved in politics. His days became more and more occupied with these pursuits and he was the object of a growing animosity which finally hounded him from England to America, where he died. Although his experimental work imposed itself with unescapeable mastery on contemporary science, his theoretical contributions were negligible. Careful scientific thought does not flourish in such an environment.

No adequate account of Priestley's work in physics seems to be available. He published in 1767 a "History of Electricity", a subject which he calls his "favourite amusement". The experiments in electricity were begun at Nantwich and the book written in Warrington, with the encouragement of Benjamin Franklin. It contains an excellent account of early work in electricity and some new experiments, as well as the argument that electric forces obey an inverse square law because of the absence of charge inside a hollow conductor. In two papers published in 1769, "On the Lateral Force of Electric Explosions", he showed that a discharge from a Leyden jar when sent through a circuit composed of a metal chain with the ends brought together so as to form a small air gap, would in part jump the air gap of high resistance rather than pass through the metallic loop. In 1772 appeared two volumes on "The History and Present State of Discoveries Relating to Vision, Light and Colours", which were not so well received as the history of electricity.

"Human happiness", Priestley tells us in a characteristically discursive preface to the "History of Electricity", "depends chiefly upon having some object to pursue, and upon the vigour with which our faculties are exerted in the pursuit". He was happy in having several objects for the exercise of his vigorous and original mind. In science he was a great explorer, opening out in his rapid and fortunate survey a great number of sites, the rich treasures of which he left to others, equipped with greater patience and knowledge, to remove, arrange, classify and interpret. Such a pioneer fills a place in the annals of human achievement, and such a one was Joseph Priestley, the bicentenary of whose birth we now gratefully remember.

Priestley's Associations with London

By H. G. WAYLING

JOSEPH PRIESTLEY knew London well. Although he officiated for several years as a Dissenting minister at Nantwich and at Leeds, before coming to reside in London as Lord Shelburne's librarian, yet he generally managed to spend a month every year in the metropolis. His friendship with men like Benjamin Franklin, Dr. Richard Price, John Canton and Andrew Kippis encouraged him, while still a provincial pastor, to study natural philosophy earnestly. He speaks of the happy hours spent in their company at the London Coffee House on Ludgate Hill, the back premises of which abutted on to the Old Sessions House in Newgate. Over their cups, these philosophical enthusiasts discussed topical questions and laid plans for prospective publications.

A few yards higher up Ludgate Hill in St. Paul's churchyard, lived Joseph Johnson, the bookseller who acted as Priestley's literary and commercial agent. Priestley's correspondence was often directed to Johnson, at whose house the itinerant cleric also occasionally lodged. Another business acquaintance on whom he called was Edward Nairne, a mathematical instrument maker to the Royal Exchange, who lived at 20 Cornhill. Nairne supplied electrical machines and air-pumps to Priestley, who, in one of his letters, directs attention to the fact that the recently imported commodity, caoutchouc, could be purchased at this establishment.

Priestley must have been very familiar with the road from the Royal Exchange to Westminster. At 36 Craven Street, Strand, where Benjamin Franklin lodged—a tablet on the house commemorates the fact—Priestley was a frequent caller, sometimes dining with the distinguished American, who, like himself, was a member of the congregation assembling at the Essex House Chapel, Essex Street, just opposite the Courts of Justice. Sometimes he preached at this church, giving a rest to his great personal friend, the Rev. Theophilus Lindsey, the officiating minister. A little to the east of the Law Courts is Chancery Lane, connecting the Strand with Holborn, and in this latter thoroughfare, at Featherstone Buildings, Priestley, as Lindsey's guest, was always *persona grata*. These buildings, which are to the west of Chancery Lane and on the north side of Holborn, are famous also as the temporary home of Sir Walter Besant, when he was a student at King's College, and at the corner house Sheridan and Miss Linley first set up housekeeping after their elopement from Bath. Another of Priestley's clerical friends was Dr. Andrew Kippis, the biographer of John Canton, the Spitalfields schoolmaster, and likewise of Sir John Pringle, P.R.S.

As a preacher with a slight stammer, Priestley would not be at his best as a rhetorician, but in the library or round the festive board, what eruditional entertainments he must have given. Can there be any doubt of the many cordial invitations he received when he came to London on his annual trip? Sometimes he stayed with Kippis in Whitcomb Street, parallel to the Haymarket, at other times with Dr. Price, who resided at Newington Green. It was this latter Nonconformist, who delivered a discourse on civil liberty at his chapel in the Old Jewry, Cheapside, which roused the ire of Edmund Burke to white heat. In the same place of worship, Priestley performed the mournful duty of preaching his friend's funeral sermon.

Having given some space to Priestley's devotional labours, it remains to mention those dealing with his scientific occupations. In 1773, he came to London as librarian and companion to Lord Shelburne, whose town residence, Lansdowne House, Berkeley Square, has recently been demolished. This post was ideally congenial to a man of Priestley's temperament and ability. The duties of his office were slight. In apartments reserved exclusively for him, he worked without let or hindrance. Distinguished foreigners paid visits to his laboratory and now and then William Pitt called on him to keep in touch with his latest experiments. At Lansdowne House on August 1, 1774, Priestley discovered oxygen, an event that will always be associated with his name.

After he left the service of Lord Shelburne, Priestley settled in Birmingham until a riotous rabble fired his house and chapel and caused him once again to seek safety among metropolitan sympathisers. Shortly after his flight to London, he was appointed to succeed Richard Price at the Gravel-pit Meeting House near Mare Street, Hackney. At this place of worship, he delivered his farewell sermon before sailing for America. His very last Sunday, however, was spent at the chapel in Essex Street, his friends "Sorrowing most of all at the words which he spake, that they would see his face no more". Next day he departed by river for Gravesend.

The Recent Japanese Earthquake

By Dr. C. Davison

ONE of the greatest earthquakes of the present century—a century that includes the Kansu earthquake of 1920 and the Kwanto earthquake of 1923—occurred off the east coast of Japan at about 5.31 p.m. on March 2, G.M.T. (or March 3, 2.31 a.m., Japanese time). The centre, as determined from the Kew record, lay in about lat. 40° N., long. 144½° E. This point is 140 miles from the north-east coast of Japan, near the foot of the western slope of the Tuscaroora Deep, the depth of water in this region being 4,000 fathoms or about 4½ miles. It is, as Prof. Milne pointed out many years ago, the seat of some of the most violent of all Japanese earthquakes. Among them may be included those of the years 1563, 1659 and 1896, and perhaps that of 1668.

This centre is so distant from land that the destructive effects of the actual shock are not as a rule important. The recent earthquake was, however, of such strength that pictures were dislodged and ornaments thrown down within a district 235 miles in length from Morioka to Maebashi. It was strongest along the 54 miles of coast between Fudai and Kamaishi. As usual in great earthquakes, the shock was of considerable duration. At the observatory of Aomori, it was sensible for eight minutes, the greatest horizontal movement registered there being 87 mm. or about 3½ in. At Tokyo, where it did not even shake down plaster or stop clocks, it was felt for four minutes.

Though much damage was caused by the

earthquake and subsequent fires, the sea-waves were responsible for the greater part. In the Iwaki prefecture, that immediately to the west of the epicentre, the sea-waves advanced in the form of a wall of water from four to seven feet in height, that swept away villages along the coast and wrecked several small towns. At Kamaishi, the sea-wall was broken down by the waves and 1,500 houses were destroyed.

The loss of life and the injury to property were considerable. According to official figures issued on March 5, 1,560 persons were killed, 956 are missing and 354 wounded; while 2,878 houses were washed away, 1,458 were thrown down, and 211 burned.

One of the most notable predecessors of the recent earthquake was that which occurred on June 15, 1896, and is known as the Sanriku earthquake. According to Omori and Hirata (*J. Coll. Sci., Tokyo Imp. Univ.*, vol. 11, pp. 161–195; 1899), its epicentre lay in lat. 39° N., long. 144½° E., or some miles to the south of that of the recent earthquake.

In Japan, as elsewhere, great earthquakes seldom visit the same region, except at long intervals of time. The centres of successive earthquakes belonging to the same seismic zone are rather displaced some or many miles—in this case perhaps sixty miles—along that zone. On land, the Sanriku earthquake was much less violent than the recent shock, though it was felt to a distance of 320 miles from its centre, but it was followed by far greater sea-waves. All eye-estimates of the height of sea-waves are subject to large errors, and we cannot have much confidence in such figures as 94 ft. at Yoshihama and 60 ft. or 100 ft. along the eastern coast of Hokkaido. At Ayukawa, however, which is 170 miles from the epicentre, the tide-gauge showed for the chief movement a rise of 8 ft. above the usual level, followed by a fall of the same amount below it. The waves were certainly large enough to be recorded at Honolulu and Sausalito, at the entrance to San Francisco Bay, the latter station being 4,787 miles from the epicentre.

In 1896, the sea-waves were far more destructive to life and property than those of the present year. In Kamaishi, 4,700 of the 6,557 inhabitants were drowned and 88 per cent of the houses were swept away. Along the whole coast affected, the number of lives lost amounted to 28,321, and of houses ruined to 6,222.

Obituary

LORD LOVAT, K.T., G.C.V.O., K.C.M.G.

THE death of Lord Lovat on February 18 will prove a great loss to forestry both in Great Britain and throughout the Empire. To his strong personality, tireless energy and great grasp of detail, Great Britain owes it to-day that she has a Forestry Commission in being, a considerable addition to the afforested area, and, it may be justifiably hoped, a settled forest policy. In future years it may come to be recognised that Lord Lovat's greatest claim to remembrance by his fellow countrymen will be the great part he played in a resuscitation of the national forestry question, which had practically lain dormant for more than a century.

Lord Lovat's interest in forestry, from a wider point of view than his own estates, was aroused before the War. In the latter part of the great struggle he acted as Director of Forestry in France, to co-ordinate the forestry operations being carried out with the object of supplying the troops in the field with the essential timber and other products of the forests. During this period, he was one of the originators of the Acland Report drawn up as a result of the Departmental inquiry, 1916–17, with the object of pressing upon the Government the paramount necessity of taking up the question of afforestation in Britain at the close of hostilities.

A Forestry Bill to this end was presented to Parliament and passed in 1919 and Lord Lovat was appointed in 1920 chairman of the Forestry Commission, which was empowered to carry out the provisions of the Bill. With the object of leaving the new Commission free from politics, a Treasury allotment was made and the Commission was not placed under a minister of the Crown.

With that energy and vitality for which he was renowned, Lord Lovat at once devoted himself to this new business, which involved commencing a planting campaign on land to be obtained from private individuals, since no State-owned land existed. That the organisation he and his Commissioners introduced was effective is proved by the fact that when he resigned the chairmanship in 1927 some 94,289 acres had been afforested and 391,511 acres of land had been acquired by the State. Before he resigned his post, with the spirit of generosity which animated him, he stated publicly: "If any good work has been done by the Forestry Commission, it does not lie with me but with the excellent body of Commissioners and staff which we have in the Forestry Commission." Yet it was an open secret that, but for Lord Lovat, the 'Geddes axe' might have brought the work of the Forestry Commissioners to an abrupt end and that on several occasions serious changes in policy were only prevented by his influence and tact.

Lord Lovat was chairman of the first Empire Forestry Conference, held in London in 1920 after the formation of the Commission, and of the second held in Canada in 1923, during which he visited most of the forests in the Dominion.

In connexion with forestry education and research, Lord Lovat held strong views which were not always in accordance with those of the universities as a whole. As a result of the Conference in Canada, he was able to give effect to his scheme of establishing an Imperial Forestry Institute at Oxford with the support of grants from the Colonial Office in London and grants from certain Dominions and Colonies. The position which the Institute has taken in the eyes of the Empire justifies Lord Lovat's prescience in this matter. He was also responsible in no small degree for the revival of scientific research in forestry problems.

In 1927 Lord Lovat became Parliamentary Under Secretary of State for Dominion Affairs and chairman of the Overseas Settlement Committee. He was also chairman of the Committees on Agriculture in the Colonies and on Colonial Veterinary Sciences. These positions he resigned in 1929.

From 1927 until his death, Lord Lovat maintained his keen interest in the forestry question in Great Britain and linked to it the broader one of Empire forestry and Empire timber marketing and development as a whole. It is perhaps not too much to say that, outside India, the position of forestry throughout the Empire and the appreciation, which is now making headway at headquarters in London and elsewhere, is due to the vital force which Lord Lovat's invigorating personality gave to it. E. P. Stebbing.

Prof. Max Wolf

Prof. Max Wolf died on October 3, at the age of sixty-eight years. He was the son of a physician at Heidelberg, and showed an aptitude for astronomy from his youth. While still at school he erected a small observatory, with an equatorial built by himself; in 1884 he discovered the interesting short-period comet that bears his name.

Wolf soon adopted photographic methods and made the first photographic discovery of a minor planet in 1891. He and his assistants afterwards added many hundreds more. The first discovery was afterwards named Brucia, in appreciation of the gift of a double camera by Miss Wolfe-Bruce. He was appointed a supernumerary professor at Heidelberg in 1893, and succeeded to the ordinary professorship in 1902. He devoted himself to photography of the nebulæ and their spectra, and was the first to detect the expanding nebula round Nova Persei in 1901; he found evidence of rotation in the nebula Messier 81, and discovered the extended nebulosity that surrounds the Pleiades.

Prof. Wolf was one of the first to use the stereoscopic method for detecting proper motions of stars, by comparison of plates taken some years apart. He published several lists of stars with large proper motions. An article by H. Vogt in *Astronomische Nachrichten*, No. 5921, pays tribute to the excellence of his teaching at Heidelberg, and his popularity.

He received the gold medal of the Royal Astronomical Society, and similar honours from many other countries. In spite of failing health, he continued at work until the last, and made several planetary discoveries in 1932.

A. C. D. C.

We regret to announce the following deaths:

Prof. Carl E. Correns, director of the Kaiser-Wilhelm Institut für Biologie at Berlin-Dahlem, Darwin medallist in 1932 of the Royal Society, on February 15, aged sixty-nine years.

Prof. E. E. Haskell, emeritus professor of experimental hydraulics in Cornell University, and dean of the College of Civil Engineering at the University in 1906–21, on January 28, aged seventy-seven years.

Dr. H. L. Snape, lately chairman of the Association of Directors and Secretaries of Education of the Union of Lancashire and Cheshire Educational Institutes, formerly professor of chemistry at University College, Aberystwyth, on March 2, aged seventy-one years.

Dr. Victor Sterki, assistant curator of Mollusca in the Carnegie Museum, Pittsburgh, since 1909, who has done much work on the anatomy, systematics and distribution of Mollusca, etc., on January 25, aged eighty-six years.

News and Views

Recommendations for Election to the Royal Society

The Council of the Royal Society has agreed to recommend for election into the Society the following seventeen candidates: Mr. P. M. S. Blackett, lecturer in physics in the University of Cambridge; Prof. J. B. Collip, professor of biochemistry in McGill University, Montreal; Col. R. E. B. Crompton, electrical engineer; Prof. H. M. Dawson, professor of physical chemistry in the University of Leeds; Dr. A. T. Doodson, associate director of Liverpool Observatory and Tidal Institute; Dr. H. J. Gough, superintendent of the Engineering Department of the National Physical Laboratory, Teddington; Mr. J. Hammond, senior assistant at the Animal Nutrition Research Institute, Cambridge; Dr. G. M. Holmes, physician to the National Hospital for Nervous Diseases, Queen Square, London; Dr. H. King, chemist at the National Institute for Medical Research, Hampstead; Prof. J. E. Lennard-Jones, Plummer professor of theoretical chemistry in the University of Cambridge; Prof. J. W. McLeod, professor of bacteriology in the University of Leeds; Dr. A. S. Parkes, physiologist, Foulerton student of the Royal Society; Prof. E. J. Salisbury, Quain professor of botany at University College, London; Dr. B. Smith, district geologist of H.M. Geological Survey; Dr. W. R. Thompson, superintendent of Farnham House Laboratory of the Imperial Institute of Entomology (London and Farnham Royal); Prof. A. M. Tyndall, Henry Overton Wills professor of physics in the University of Bristol; Prof. J. H. M. Wedderburn, professor of mathematics in Princeton University.

Elections to the Royal Society of Edinburgh

THE following were elected fellows of the Royal Society of Edinburgh at a meeting held on March 6: Dr. F. L. Arnot, lecturer in natural philosophy in the University of St. Andrews; Major P. C. Banerjee, Indian Medical Service; Mr. J. L. Begg, treasurer and past vice-president of the Geological Society of Glasgow; Dr. T. R. Bolam, lecturer in chemistry, University of Edinburgh; Mr. Finlay J. Cameron, general manager, Caledonian Insurance Company, Edinburgh; Mr. J. I. Carswell, lecturer in engineering, University of Edinburgh; Dr. A. M. Clark, lecturer and director of studies, University of Edinburgh; Dr. A. L. Craig-Bennett, lecturer in zoology, University of Edinburgh; Mr. E. G. Dymond, Carnegie research fellow and lecturer in natural philosophy, University of Edinburgh; Mr. J. M. Erskine, general manager, Commercial Bank of Scotland, Ltd., Edinburgh; Dr. Thomas Ferguson, H.M. medical inspector of factories, Home Office; Prof. C. Forrester, Department of Chemistry and Assaying, and acting Principal, Indian School of Mines, Dhanbad; Dr. W. H. Fowler, medical radiologist, Edinburgh; Mr. A. W. de R. Galbraith, city engineer, architect and surveyor, Christchurch, New Zealand; Mr. A. C. Gardner, chief engineer, Clyde Navigation Trust, Glasgow; Dr. R. P. Gillespie, lecturer in mathematics, University of Glasgow; Mr. T. H. Gillespie, director-secretary, Zoological Society of Scotland, Edinburgh; Mr. W. G. Guthrie, assistant in applied mathematics, University of St. Andrews; Lieut.-Col. E. E. Hume, Medical Corps, United States Army, librarian of the Army Medical Library, Washington, D.C.; Dr. D. Lees, clinical medical officer, Corporation of Edinburgh and surgeon in charge of venereal diseases, Royal Infirmary, Edinburgh; Mr. J. Macleod, manager, Glasgow Corporation Chemical Department; Prof. J. Malcolm, Department of Physiology, University of Dunedin, New Zealand; Mr. W. J. M. Menzies, inspector of salmon fisheries of Scotland, Fishery Board for Scotland, Edinburgh; Prof. L. M. Milne-Thomson, assistant professor of mathematics, Royal Naval College, Greenwich; Dr. J. Murray, Rector, The Academy, Annan; Mr. T. Nicol, lecturer in anatomy, University of Glasgow; Mr. C. W. Parsons, lecturer in zoology, University of Glasgow; Mr. A. W. N. Pillers, chief veterinary officer, Corporation of Liverpool and lecturer on veterinary parasitology, University of Liverpool Veterinary School; Mr. F. A. B. Preston, lecturer in municipal engineering, Town Planning, etc., Royal Technical College, Glasgow; Mr. J. L. Somerville, auditor to the University of Edinburgh; Dr. J. B. Tait, junior naturalist (hydrographer), Fishery Board for Scotland, Aberdeen; Mr. G. Taylor, assistant keeper, Department of Botany, British Museum; Dr. G. Timms, lecturer in mathematics, University of St. Andrews; Prof. J. M. Watt, Department of Pharmacology and lecturer in dental materia medica, University of the Witwatersrand, Johannesburg; Dr. W. F. J. Whitley, medical officer of health, Northumberland County Council; Mr. J. Wright, Kirkcaldy.

Centenaries of Priestley and Pepys

THE bicentenary of the birth of Joseph Priestley occurs on March 13, and elsewhere in this issue we print articles discussing his scientific work and describing his visits to London. A few weeks ago (NATURE, Feb. 18), reference was made to the association of Samuel Pepys with the Royal Society, the tercentenary of whose birth fell on February 23. Bicentenaries and tercentenaries of scientific interest are not of frequent occurrence and the Royal Society is marking the occasion by an "At Home" at 9 o'clock on Wednesday, March 15. With further reference to the article on Pepys Mr. Edwin Chappell, 41 Westcombe Park Road, London, S.E.3, has provided us with references showing that Pepys's birthplace was definitely in London. On this subject W. H. Whitear, in "More Pepysiana" (1927), says: "From information derived from the parish books of St. Bride's, Fleet Street, it seems to be beyond doubt that Samuel was born in his father's house in Salisbury Court". It is of interest in this connexion to give the record which appears in "Alumni Cantabrigienses" (Venn, 1924) against Pepys's name: Adm. pens. Trinity Hall, June 21, 1650. B. at Brampton, Feb. 23, 1632–3. Migrated as scholar to Magdalene, Mar. 4, 1650–1; Matric. 1651; B.A. 1653–4; M.A. 1660.

Carsten Niebuhr, 1733–1815

ON March 17 occurs the bicentenary of the birth of the famous German traveller, Carsten Niebuhr, who was the only survivor of the Danish expedition sent to examine the monuments and antiquities of the Orient in 1761. Born in the village of Lüdingworth in the Duchy of Lauenborg, Niebuhr appeared destined to follow in the footsteps of his forbears, who were small landowners. On coming of age, however, he spent his small patrimony in obtaining instruction in mathematics and by 1757 was a student at Göttingen, where he was afterwards taught the new methods of determining longitude by lunar observations by Tobias Mayer himself. Niebuhr made great use of this method in his travels in the East which occupied the years 1761–1767. After his return to Europe he commenced the publication of the account of his travels, married and, being given an official post in the town of Meldorf in Holstein, settled there. He was made a Danish councillor of State, a knight of the Daneborg and in 1802 was elected an associate of l'Institut de France. Towards the end of his life he became blind and lame. He died at Meldorf on April 26, 1815. His son, Barthold Georg Niebuhr (1776–1831), was a distinguished historian and archæologist and his grandson, Marcus von Niebuhr (1817–1860), an eminent Prussian official.

THE expedition which made Niebuhr famous was undertaken by the Danish Government at the instigation of the German orientalist, Johann David Michaelis (1717–1791), one of the first to study the biblical narratives as a part of Oriental history. The other members of the expedition were von Haven, a linguist, Peter Forskål, a Swedish naturalist, Dr. Cramer, a physician, and Bauenfeind, a draughtsman. Leaving Denmark in a warship at the beginning of 1761, the party first visited Constantinople. From September 1761 until October 1762 the travellers were in Egypt, where Niebuhr determined the positions of Cairo, Rosetta and Damietta, made maps of the Nile and measured the Pyramids. Embarking at Suez, another year was spent in the Red Sea and Arabia. Most of the members, however, had been attacked with sickness; von Haven died in May 1763, Forskål in July, Bauenfeind in August and Cramer in February 1764. Niebuhr alone was left. By then he was at Bombay. About a year later Niebuhr set out on his return journey, visiting Persia, Mesopotamia and Syria, and after seeing Cyprus, Jerusalem and Damascus, he again reached Constantinople in February 1767. Three months were spent in studying the military and civil statistics of Turkey and Niebuhr then journeyed back to Denmark via Wallachia, Moldavia, Poland and Prussia. His "Descriptions of Arabia" was published in 1772 and this was followed a year or two later by his "Travels in Arabia and the Adjacent Countries". In June 1795 a fire at Copenhagen destroyed the copper-plates for the third volume and this was not published until twenty-two years after his death.

Centenary of Hilary Bauerman, 1833–1909

HILARY BAUERMAN, who was born in London on March 16 a century ago, had an international reputation as a geologist and metallurgist. He made geological surveys in many parts of the world, acted as juror at various international exhibitions, published widely read textbooks, and at his death left his fortune for the furtherance of the study of mineralogy. His parents, who were of German nationality, came to London in 1829. At the age of eighteen years, in 1851, Bauerman became one of the seven original students of the School of Mines in London, studying under Playfair, Ramsay, Forbes, Warington Smyth and others. He also spent three years at the Freiburg Mining Academy and then on returning to England joined the Geological Survey of Great Britain. His overseas work began with his appointment as geologist to the North American Boundary Commission. In 1868 he published his "Metallurgy of Iron", in 1883 became lecturer in metallurgy at Firth College, Sheffield, and in 1888 succeeded Prof. Percy as professor of metallurgy at the Ordnance College, Woolwich. He was elected an honorary member of both the Iron and Steel Institute and Institute of Mining and Metallurgy. He died unmarried at his house in Balham on December 5, 1909, and was buried in Brookwood Cemetery.

Harrison's First Marine Timekeeper

IN connexion with his efforts to make a timekeeper which would keep time accurately at sea, John Harrison made four instruments, one in 1735, a second in 1739, a third a few years later, for which he was awarded the Copley medal of the Royal Society, and a fourth which, after being tested on a voyage to Jamaica and back lasting from November 18, 1761, until March 26, 1762, caused him to be adjudged as having won the £20,000 reward offered through the Act of Parliament of 1714. There was much delay in paying Harrison and it was laid down that all four of his time-keepers were to be handed over to the Royal Observatory. These time-keepers naturally were soon superseded by better instruments, and they ceased to be used and fell into disrepair. Some twelve years ago, however, Lieut.-Comdr. Rupert T. Gould obtained permission to recondition them and he has now completed his labours by the restarting of Harrison's first marine timekeeper, made in 1735, but not used since 1767. All four of Harrison's instruments are thus again in working order, and according to an article in the *Times* of February 28, No. 1 will be kept going in an air-tight show-case. Needless to say, this instrument bears little resemblance to a modern chronometer. It weighs no less than 70 lb. Tested aboard H.M.S. *Centurion* and H.M.S. *Orford* in 1736, however, it gave satisfactory results, and on the voyage home, when the *Orford* sighted land the reckoning by the clock showed the position of the ship to be off the Lizard, while the ordinary methods of navigation gave the ship's position as off the Start. The former proved to be the correct position.

Prof. B. Němec

PROF. B. NĚMEC, director of the Plant Physiological Institute of the Charles University, Prague, celebrates his sixtieth birthday on March 12. Prof. Němec is a well-known plant physiologist, working especially in experimental cytology and caryology, anatomy and experimental morphology, physiology of fertilisation and genetics, on symbiosis and parasitism, plant pathology, regeneration and other aspects of plant physiology. His statolith theory in plants is widely known, and also his more recent discoveries, by the use of chloral hydrate and other agents, concerning artificially induced mixoploidy and polyploidy in plants. Prof. Němec is well known to English scientific workers. In 1927 he lectured at University College, London, and he has attended many scientific meetings in England, the last occasion being the Fifth International Botanical Congress at Cambridge in 1930. Prof. Němec is a foreign member of the Linnean Society of London and also of many other learned societies of his own and other countries.

Sir Robert Hadfield and the Academy of Sciences of the U.S.S.R.

AT the luncheon given to Sir Robert Hadfield on February 28 by M. I. Maisky, the Soviet Ambassador in London, in honour of the election of Sir Robert as an honorary member of the Academy of Sciences of the U.S.S.R., it was recalled by M. Maisky that in 1831, Michael Faraday was also elected an honorary member of the Academy. Such events emphasise the internationalism of science. In Russia, since the revolution, new scientific institutes, laboratories and universities have been built, and science has made great progress; metallurgy in particular has been encouraged. In this work, Russia readily accepts foreign assistance. In his reply, Sir Robert Hadfield said that, to him, Russia is the land of Mendeléeff, whose work has been of fundamental importance in chemistry. He also spoke of the work of the well-known Russian metallurgist, the late Demetri Tschernoff, who did pioneer work on the metallography and scientific heat treatment of steel at a time when only empirical methods were used. His work, introduced to Great Britain by the late Sir William Anderson, led to the formation in 1881 by the Institution of Mechanical Engineers, of a special committee, of which Tschernoff was himself a member, to report on the heat treatment of steel; this committee is still in existence as the Alloys Research Committee. Referring to the Iron and Steel Institute, Sir Robert pointed out that there are, at present, fourteen Russian members, and he expressed the hope that this number will be increased, with the future developments of science in that country. Sir Robert Hadfield's name is, of course, associated with manganese and silicon steels, and when speaking of Russia's vast mineral resources, he naturally singled out manganese, which is much used in the production of high quality steel as well in the special alloy steels. Enormous deposits of this manganese ore occur in the valley of the Kvirila River, and Sir Robert anticipates heavy production during the next twenty years. Sir Robert concluded with a tribute to the interest in scientific development which is being shown in Russia.

Locomotion in Sponges

A NEW and valuable light was thrown on the vexed question of locomotion in sponges by Mr. M. Burton at a meeting of the Zoological Society on February 21. Mr. Burton had been asked to investigate some sponges growing on the filter-beds of the Society's Aquarium, as it was feared these might interfere with the circulation of the water. He found that even the adults were capable of moving appreciable distances to secure a more favourable area for feeding. Movement in post-larval, and young sponges, he pointed out, had been recorded on several occasions; but it was now apparent, for the first time, that even fully-grown individuals could change their position. This discovery has an important bearing on our conceptions of the biology of sponges. So far from being 'typically sedentary animals', as they are described in textbooks—the victims of chance and circumstance—it is now established that they can, or at least in some species, exercise some selection as to habitat, the movement being a directive locomotion, carried out by amœboid extensions of the ectosome.

THIS new discovery by Mr. Burton follows hard upon his observations on unattached sponges, published in the "Discovery" reports 1932, wherein it is shown that some species, and individuals of many other species, habitually lead a free existence, and are capable of being transported by currents. In this respect his observations on the sponges in the filter-beds in the Aquarium of the Zoological Gardens are particularly interesting. The individuals of this species, as yet unnamed, are very easily detached by small Crustacea, and are sufficiently buoyant to move several inches, in still water, as the result merely of a shrimp swimming by. Thus, at all ages, either by their own movement, or by being transported by currents, sponges are far from being the irrevocably fixed animals they have hitherto been supposed to be.

Australian Dairy Cattle Research Council

THE dairying industry in Australia is becoming alarmed at the prevalence of contagious abortion and contagious mastitis (mammitis) in milking herds. At the instance of the pure-bred cattle breeders of New South Wales, an Australian Dairy Cattle Research Council has been set up with headquarters in Sydney and a liaison committee in each State. It will work in close association with the Commonwealth Council for Scientific and Industrial Research and the State Departments of Agriculture, but will seek its funds from other than government sources and will be free from political control. The Australian Dairy Council, a body concerned mainly with marketing problems, has promised £2,000 a year for five years towards the cost of investigations, and other contributions are confidently expected. The work on abortion will be centred at the Glenfield Veterinary Research Station in New South Wales, while the mastitis work will be carried on in Victoria, probably with the University of Melbourne as headquarters.

Ritual at Ur

MR. C. L. WOOLLEY's first report on the excavations of the current season at Ur (*Times*, March 3), dealing mainly with a building of the little-known First Dynasty, about 3000 B.C., below the platform of Ur-Engur's ziggurat, records several features which are new, some of them by no means readily susceptible of explanation. It would appear that a ziggurat, now sheathed in the later tower, occupied the middle of a platform, in the north and east corners of which were temples of the moon god. In describing the eastern temple, Mr. Woolley directs attention to the extraordinary thickness—some fifteen feet—of the brick floor of the approach chambers which led to the open ziggurat terrace. For this, the only explanation he has to offer is that it had some religious purpose. Again, in the courtyard are two circular structures of brick, which would be regarded as bases for columns, if it were not for their great diameter of thirteen feet. The suggestion that they were intended as the bases for altars is supported by the existence nearby of a brick-built basin sunk in the floor. In an adjacent room is a circular hearth for the great cauldron in which the food of the god was prepared.

Another curious piece of ritual, if Mr. Woolley's interpretation be accepted, is brought to light in a later building, which lay over the First Dynasty temple. Here were found four pits of some size—one rectangular pit is 15 ft. by 12 ft.—sunk in the floor. Three pits, one circular and two square, had been filled with clean red earth, the fourth rectangular pit had a layer of red earth superimposed on three layers of carefully laid gypsum blocks. Mr. Woolley offers the suggestion that these pits were intended for the foundations of altars, and aptly cites the "clean earth" which the old Sumerians brought for the foundations of their temples.

Corpus of Egyptian Pottery

TENTATIVE proposals for the compilation of a complete corpus of Egyptian pottery, which were discussed at Cairo in 1931, have now taken practical shape. A scheme has been drawn up by a committee consisting of Mr. Guy Brunton, Dr. Junker of Vienna and Mr. O. H. Myers. Excavators are to be supplied with cards on one side of which a print or drawing of the pot is to be affixed, and on the other information relating to it is to be given under a number of heads. These slips, when completed, will be returned to the editor of the corpus, Mr. G. L. Harding, or, during his absence while excavating at Lachish, to Mr. O. H. Myers of the Egypt Exploration Society. The scheme of the corpus is based upon the "Predynastic Egyptian Corpus" issued by Sir Flinders Petrie in 1921, as supplemented by the additional material obtained by Mr. Brunton in his Badarian excavations. It is, however, to be continued beyond these limits to the Arab period. The co-operation has been secured of the Egyptian Antiquities Service, the French, German and Italian institutes, the Egypt Exploration Society, the Oriental Institute of the University of Chicago and nearly all the other bodies represented in the archæological exploration of Egypt.

An Experimental Air-Map

WITH the view of devising a suitable system of cartography for aviators the American Geographical Society has constructed an experimental sheet of the Pittsburgh-Cleveland area on a scale of 1 : 500,000, which is published in the *Geographical Review* for January 1933 with accompanying text by Mr. O. M. Miller. Since the drainage system is the most conspicuous guide to an airman, all water is shown in white against a background of grey, varying tints of which are used to show the surface relief. The darkest tint, contrary to custom, shows the lowest ground. White spot heights are at water-level and black spot heights at the highest points in any area. Conspicuous relief features, such as bold escarpments, are marked by black hachuring but this seems to be sparingly used. A general description of surface conditions has been attempted such as "farming country", "forested uplands", etc. Railways in black and roads in green stand out well. Red is used exclusively for objects dangerous to flying, including built-over areas, power transmission lines and oil tanks. Air ports, beacons and lighthouses are shown in yellow. Air ports are named in black, other place-names being in red. The projection used is the modified polyconical. Meridians and parallels and lines of magnetic declination are omitted from the main map and shown on a key map in the margin. The American Geographical Society invites criticisms of this sheet from aviators.

Institute of Chemistry of Great Britain and Ireland

AT the fifty-fifth annual general meeting of the Institute of Chemistry held on March 1, the Meldola medal was presented to Dr. L. E. Sutton, of Oxford, and the Sir Edward Frankland medal and prize to Mr. L. Young, of the Royal College of Science. In moving the adoption of the report of Council, the president, Dr. G. C. Clayton, remarked on the increasing activity of the Institute. Dr. Clayton pointed out that for positions of control, science alone does not suffice : the chemist must acquire much knowledge and experience and become endowed with those not less-important qualities of character, judgment and tact, which responsibility entails. Not only competition, but also discovery and invention, together with modern methods in administration and management, have contributed to the existence of conditions which are bewildering to economists and financiers. These difficulties are not new : they were present when the mechanisation of industry started but have not become more acute. It is for chemists to put our old industries in the most favourable position to meet competition, and even more to branch out into new lines, especially new industries, which, by giving employment, will absorb some of those displaced by world competition in many of the heavy industries. Prof. J. F. Thorpe was elected president of the Institute in succession to Dr. Clayton.

Recent Investigations in Nutrition

THE Minister of Health has directed the attention of county and county borough councils and other maternity and child welfare authorities to certain recent investigations and the recommendations of the Advisory Committee on Nutrition based on them (Circular 1290 : 1932 : H.M. Stationery Office. Price 2*d*. net). They deal with Dr. Helen Mackay's work on the nutritional anæmia of infancy, Prof. and Mrs. Mellanby's researches on the etiology of rickets and dental decay and Dr. Corry Mann's experiment on the effects of additional milk in the diet of schoolboys. For preventing nutritional anæmia, it is recommended that iron ammonium citrate should be added to the milk given to infants or that a dried milk containing added iron should be used. It is pointed out that severe rickets is rapidly disappearing in Great Britain, but that in some areas the milder form of the disease is still prevalent. Faulty dentition is widespread. The importance of the diet of pregnant and nursing mothers and of infants and young children containing a sufficient amount of calcium, phosphorus and vitamin D is therefore emphasised. Of these, vitamin D is the most likely to be deficient. The diet should contain fat fish such as herrings, sprats or mackerel, fish livers, egg yolk, milk and butter; if margarine is used, a brand containing added vitamins A and D should be employed. Cod liver oil and bone ash will also make good a deficiency in vitamin D, calcium and phosphorus. As regards milk, the circular urges local authorities to take every opportunity of directing attention to the merits of milk as a food and of stimulating its increased use as an article of diet for children.

Costs of Electricity Supply and Distribution

IN an endeavour to foretell the future of electricity supply and distribution in Great Britain, Mr. J. M. Kennedy and Miss D. M. Noakes have made an elaborate analysis of the statistical returns issued by the Electricity Commissioners during the last ten years. They explained the conclusions arrived at in a paper read to the Institution of Electrical Engineers on January 26. They divide the capital invested into two parts, the first giving the costs of generation and the second the costs of distribution. The results show that the distribution side of electric supply is becoming the more important. They have also reviewed the revenue derived from the sales of electricity and allocated it between generation and distribution expenses. The figures show that although the efficiency of generation has increased materially, there has been little, if any, improvement in distribution efficiency. The cost per kilowatt installed during the last ten years has diminished from £25 to £20. This is probably due to the increase in the size of the turbine and boiler units installed. If it is assumed that the percentage of spare plant required would be 83 without the grid and 20 with the grid, the amount of spare plant released in five years time would be sixty million pounds in capital. As the sales of units per pound of distribution capital increase, the ratio of the distribution costs to the total costs decreases substantially. Whilst the distribution capital is increasing at the rate of 18 millions a year, the generation capital is only increasing at the rate of 7 millions. The authors state that if the companies offered sufficiently attractive tariffs, there seems no reason why the total domestic consumption should not be twice the present total sales for all purposes. If company control is decided on, a satisfactory scheme for the regulation of prices and dividends will have to be established. Any undue increase in the average remuneration of capital will inevitably keep up the price of electricity and retard development.

Image of the Physical World in Cinematography

THE two dimensional world of light and shadow projected upon the screen of a cinema theatre is something quite unique and is essentially different from our own material world of reality. In *Scientia* for January, Mr. Torahiko Terada states that future cinema techniques could be anticipated by a careful study of these two kinds of worlds. He considers that the marvels of the cinema film depend mainly on the element of time. When the relative scale of time in the physical world and the screen world is changed we receive a shock. For example, we can see the seed of a flower growing up into full blossom in a few minutes or a bullet emerging from the muzzle of a gun accompanied by a retinue of vortices and waves. This change in the scale of time brings with it the corresponding change in every physical quantity depending on the time. When a scene of a collapsing brick chimney is projected with half the natural speed, its acceleration will only appear to be a quarter its natural value and the value of gravity will apparently be only a quarter its true value. C. F. Flammarion once dreamed of the possibility of reviewing the world's history in its reverse order by flying out of our earth with a velocity greater than that of light. The principle of relativity prohibits this, but, in the screen world, history may run easily in its reverse order. In our visual effect it is practically the perfect reversal of time. It may be considered a materialised extension of our memory. It is impossible to tell in what direction a pencil balanced on its point will fall but in the reversed film it will stand upright as nearly perpendicular as possible. On the other hand, in a reversed film we cannot tell the direction in which a billiard ball at rest on the table is going to move. The reversal of time as realised in the cinema is a straightforward denial of the second law of thermodynamics—the only law prescribing the sequence of the physical world.

New Britain

To those who believe that the present situation is a challenge to thought and that reconstruction demands fundamentally both clarity of thought and the readiness to discard preconceived ideas or established customs or institutions, when these stand in the way, the new quarterly journal, *New Britain*, should make a strong appeal. Its pages are characterised by a freedom from prejudice and a capacity for courageous and independent thought worthy of an organ aiming at national renaissance and in harmony with the spirit of the Oxford reformers to whom we owe the English Renaissance of the sixteenth century. Scientific workers will be particularly interested in the articles which attempt to assess the place of science in the new order. Mr. Gerald Heard, in his article on "Eugenics and the New Order", directs attention to the part which eugenics must play, pointing out that lack of will-power prevents use being made alike of the plans of leaders or the 'stones' provided by science. Prof. F. Soddy discusses the physical foundations of civilisation and the dangers attending a policy of drift and failure to abandon the old herd instincts of poverty and scarcity and methods of dominance based upon them. Dr. G. Scott Williamson in his article on "The Scientists' Outlook" deals particularly with the place of biological science in the new order of society and the dangers of palliatives as against a positive and thoroughgoing policy. The cultural aspects of science and its place among human values are discussed in thought-provoking essays by S. G. Hobson and Philip Mairet. The whole of the January-March issue places a welcome emphasis on the social and human values of science and the positive benefits which it might yet confer on mankind.

Voyage Around Franz Josef Land

The remarkable feat of circumnavigating the ice-girt Franz Josef Land in a small motor vessel is reported by Science Service of Washington, D.C. Prof. N. N. Subov, arguing from temperatures in the Barents Sea in recent years that the arctic branch of the North Atlantic drift was unusually warm and would reduce the amount of ice around Franz Josef Land, set out last August from Murmansk in a hundred ton motor boat with 30 days' fuel and 40 days' stores. The tour, which was made from east to west, actually took thirty-four days. A large number of soundings and salinity observations were taken. A few small corrections in the map were also made.

Announcements

Sir Richard Glazebrook, formerly chairman of the Aeronautical Research Committee, has been awarded the gold medal of the Royal Aeronautical Society.

At a meeting of the Council of the Royal Society of Edinburgh held on March 6, the following prizes were awarded: The Makdougall-Brisbane prize for 1930–32, to Dr. A. C. Aitken, of the University of Edinburgh, for various contributions to mathematics published in the *Proceedings* of the Society; Gunning Victoria Jubilee prize, for 1928–32, to Sir James Walker, for his numerous contributions to physical and general chemistry. The Bruce-Preller lecture for 1933 will be delivered by Prof. C. H. Lander, on October 23, on the subject of the utilisation of coal.

Mr. P. M. S. Blackett will deliver the G. J. Symons memorial lecture of the Royal Meteorological Society on March 15 at 7.30. The subject of the lecture will be "Cosmic Radiation".

The annual general meeting of the British Medical Association will be held in Dublin on July 25–29, under the presidency of Prof. T. G. Moorhead, regius professor of physic at Trinity College, Dublin.

A symposium on the utilisation of coal has been arranged by the British Science Guild, to be held on March 27 at the Royal Institution under the chairmanship of Mr. H. T. Tizard. The speakers include Capt. B. Acworth, Mr. S. Lacey, Eng.-Rear-Admiral W. Scott Hill and Mr. A. C. Hardy. The discussion will be opened by Dr. O. M. W. Sprague.

The Committee on Thermochemistry of the Union Internationale de Chimie proposes to publish an international table of thermo-chemical data. The Secretary of the Committee would be glad if authors who have published papers on thermochemistry within the last five years would send him two copies of their papers. Such copies should be sent to Dr. L. J. P. Keffler, The University, Liverpool.

At the annual general meeting of the Society of Public Analysts held on March 1 the following officers were elected for 1933:—*President:* Mr. F. W. F. Arnaud; *Past Presidents on the Council:* Mr. E. Richards Bolton, Dr. J. T. Dunn, Dr. Bernard Dyer, Mr. Edward Hinks, Mr. P. A. Ellis Richards, Mr. G. Rudd Thompson, Dr. J. Augustus Voelcker; *Vice-Presidents:* Mr. John Evans, Mr. H. M. Mason, Dr. G. W. Monier-Williams, Mr. George Stubbs. *Hon. Treasurer:* Mr. E. B. Hughes; *Hon. Secretary:* Mr. G. Roche Lynch.

In the paragraph in Nature of March 4 (p. 300) entitled "Photographic Analysis of Explosion Flames", the velocity of detonation is incorrectly given, through an error in typing, as "one or two metres per second"; it should read "one or two miles per second".

Under the terms of the Thomas Gray Memorial Trust, the Council of the Royal Society of Arts has awarded the £100 prize, offered in 1932 for an essay on the rescue, by another vessel, of passengers and crew of a sinking vessel, to be equally divided between Commander R. D. Binney, Chief Officer J. W. Murphy, Lieut.-Commander D. A. Stride and Lieut.-Commander J. H. Walker. For the £100 prize offered for any valuable improvement in the science or practice of navigation, nothing of sufficient merit was submitted, but an award of £50 was made to Able-bodied Seaman J. Patteson for a device designed by him and entitled "The Harmonic Constant Tide Calculator".

Seismometrical reports on the earthquakes felt and recorded in Tokyo are now issued by the Earthquake Research Institute. We have received the first two numbers dealing with the earthquakes of January–June, 1932. Each of them includes a map of the origins of the earthquakes (thirty in number) felt in Tokyo, showing that they lie in, and to the north of, the Bay of Tokyo, except four in the well-known zone that lies under the Pacific to the east of the Boso peninsula. Copies of the more important seismograms are also reproduced.

Applications are invited for the following appointments on, or before, the dates mentioned:—An assistant engineer for the River Avon (Bristol) Catchment Board—The Clerk and Solicitor to the Board, The Council House, Bristol (March 13). A principal of the Gloucester Technical College—The Clerk to the Governors, 24, Barton Street, Gloucester (March 16). An assistant borough electrical engineer and a temporary constructional engineer in the Electricity Department of the Fulham Borough Council—The Town Clerk, Town Hall, Fulham, S.W.6 (March 16). A divisional engineer (electrical) in the Department of the Chief Engineer of the London County Council—The Clerk of the Council, The County Hall, Westminster Bridge, S.E. (March 17). A lecturer in medicine at the University of Aberdeen—The Secretary (March 21). A professor of civil engineering at Trinity College, Dublin—The Secretary of the University Council (March 31). A ballistic assistant for mathematical work in relation to trajectories of projectiles—The Secretary (C.E. Branch), Admiralty, S.W.1.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Presence of a Bacteriophage for *B. salmonicida* in River Waters

EPIDEMICS of "Furunculosis of the Salmonicidæ" generally attributed to a well-defined bacterium—*B. salmonicida* (Emmerich and Weibel, 1894)—have been the cause of a high mortality among salmon and trout in England during recent years and have been difficult to deal with owing to a lack of knowledge of the epidemiology of the disease and particularly of the reservoirs of the infection during inter-epidemic seasons. The problem of following out the infection is not easy as *B. salmonicida* has no saprophytic existence in river water, in which it does not live for more than a few days, so that it is useless to attempt the isolation of the bacillus from the suspected water—even if this were a practical possibility. Moreover, the absence of sick or dead fish does not exclude the possibility of infection, as apparently healthy fish are known to act as carriers of the disease and to be capable of spreading the infection.

It seemed possible that, if the infection of fish is associated with the appearance in the water of a specific bacteriophage, this might prove a useful index for tracing the infection. This aspect of the problem does not appear to have been considered, and as no reference to a phage for *B. salmonicida* could be found in the literature, the matter seemed worth looking into, and a search was made in a number of natural waters.

Examination of the water of the Thames at Kingston during the summer of last year showed the presence of a bacteriophage highly active for *B. salmonicida*, and the phage could be demonstrated in volumes as small as 0·3 c.c. of the water. The waters of several other rivers were then tested and active phages for *B. salmonicida* were isolated from the upper reaches of the Mole in Surrey, from the Arun and the Ouse in Sussex, and from the Avon at Bath.

The water of the Arun was interesting as it yielded two apparently distinct phages. One of these, which is highly active, forms small plaques (about one millimetre in diameter) on 1 per cent agar, and continues unchanged after repeated passages with *B. salmonicida*. The other, which is less active, at first forms larger plaques (about two to three millimetres in diameter), but on repeated passages with *B. salmonicida* gives both large and small plaques.

In a sample of water from the Burn of Houlland, North Roe, Shetland, kindly sent me by Capt. S. R. Douglas, no active phage could be demonstrated in 10 c.c. of the water. Control examinations of the tap water of the National Institute for Medical Research and of the Whitestone Pond, Hampstead, showed no active phage in 250 c.c.

The recognition of an active phage as a rule gives no difficulty, the plaques formed on agar being quite definite and unmistakable. Occasionally very feeble phages are encountered which, even after repeated passage with *B. salmonicida*, show only very faint and scarcely discernible plaques on agar. Whether these feebly active strains are true salmonicida phages appears doubtful, and for the purposes in question they may probably safely be ignored.

The presence of an active phage for *B. salmonicida* in the waters of a number of English rivers is highly interesting and its connexion or otherwise with the presence of infected fish would appear worthy of investigation as, if such a connexion were established, some measure of control might at once be possible particularly in the case of hatcheries, since apparently healthy fish from these have been incriminated as responsible for the spread of the disease. In this connexion the periodical examination (for the presence of the phage) of the effluent of a hatchery supplied with phage-free water might give valuable results.

CHARLES TODD.

National Institute for Medical Research,
Hampstead.
Feb. 27.

Origin of Angiosperms

IN various notes in *Science* and in my longer studies of cycadeoids, the view is maintained that the angiosperms must be very old, and in so far as not actually discrete, related to the older flowering gymnosperms. Such views of descent relegate gnetaleans to the position of a side or blind line as suggested by Seward. The group was even held to be angiospermous by Lignier and Tison. In any event, it pictures in a lively manner some of the types of change both vegetative and reproductive which must mark the evolution of the angiosperms from homoxylous freely flowering forerunners.

Primarily, the view of a cycadeoid rather than a cordaite or conifer explanation of angiosperm derivation rested on floral evidence taken with the sharp resemblance between the cycadeoid wood and that of the Oriental dicotyledonous family Trochodendraceæ, which could be shown to have a defined relationship to the magnolia group proper. Branching and habit presented no difficulty, as the small flowered *Williamsoniella* and *Wielandiella* bridged that gap. Nor was there any marked doubt as to either the time or general mode of origin of netvenation; while *Caytonia* afforded the needed example of a very primitive, even if much isolated, angiospermous carpel with cycadeoid-like seeds.

New evidence, slow to come, had to be awaited. Here the hope of floral discovery was a slender one; while the small and primitive types of cones are as little seen as the flowers, and without more intensive methods of search or some utterly unawaited 'finds', any crucially important types of either might not appear in another fifty years. Moreover, it was obvious that the petrified record of the angiosperms is very greatly limited by an easy liability to bacterial decay. In short, the nearest points of awaited discovery became: (1) determination of wood structure in the small-stemmed cycadeoids (*Williamsoniella, Wielandiella*) as probably dependent on the materials in mid- to lower Mesozoic lignites; (2) extension of knowledge of wood structure in the Trochodendraceæ and their allies back in geological time.

Now at this point, in the latter part of 1932, a turn in the long road has been made. Fr. J. Mathiesen, in an account of fossil plants from East Greenland[1], describes from Cape Dalton, lat. 69° 30′ N., certain calcified stems of good definition which are compared with the existent *Tetracentron*, hence *Tetracentronites*.

Accompanying them there is a *Corylopsis*-like type, *Corylopsites*. The age of these most significant new woods is Palæocene-Eocene. Also, B. Sahni[2] gives a description of a so-called new genus *Homoxylon* based on a portion of a larger stem from the mid- or lower Jurassic of the Rajmahal Hills. Unfortunately the exact locality of this likewise important wood, the original of which I have seen in thin section, is not yet determined, although there is no reason to doubt its Jurassic age. Sahni compares his new genus with *Trochodendron.*

So close is the structural resemblance between these new fossils that it appears to I. W. Bailey, who in a recent letter first directed my attention to the paper of Mathiesen, as if the generic analogy were reversed. That is, Bailey would compare the Greenland fossil with *Trochodendron*, the Indian with *Tetracentron*. However this may be, both these types, though so far separated in latitude and time, are in remarkable agreement with the magnolian woods, and both present a further and most striking resemblance to the wood of such species of the cycadeoids as *Cycadeoidea Dartoni*, *C. Wielandi*, *C. Painei* (or *Paynei*), *Raumeria Reichenbachiana*, and *Bennettites* (or *Cycadeoidea*) *Gibsonianus*. In fact, were these latter woods alone known without reference to foliage or fructification, they could at most be set aside as of a family directly related to the Trochodendraceæ. Also it must be remembered that many of the cycadeoids were microphyllous, and that *Drimys* is exstipulate. The only possible doubt as to the main position of the new Greenland and Indian types thus arises from the close agreement of the wood structures with those of such old and obviously specialised types as the cycadeoids just cited.

Comparison of the homoxylic (vessel-less) angiosperms with cycadeoids depends much on the region next the pith. *Drimys*, with thick-walled ray cells, and clear transition from well-defined scalariform to pit wood, is here the fundamentally important type; while consideration of the heteroxylic *Liriodendron* further shows how the simpler scalariform elements are transformed into vessels. The cycadeoids of reference here are those amongst the many species studied which in occasional specimens or parts of such in exceptional preservation show both ray and tracheidal features in full detail. Thus in *Cycadeoidea Dartoni* there is seen the most remarkable transition from scalariform to pit wood, exactly comparable to that figured by Mathiesen in the Greenland *Tetracentronites*. Again, in the radial sections from the mid-region of the United States National Museum type, *Cycadeoidea Paynei*, preservation of both ray and tracheidal elements is perfect, the structure-parallel of both with *Tetracentronites* complete. Likewise these features are seen in an equal beauty of preservation and identity amongst the very different, small-flowered, free-fruiting and geologically much younger cycadeoids of the Mesaverde of the San Juan Basin of New Mexico. In all the foregoing, the scalariform-pit wood transitions, and the thickened ray cells are present. That is, this structural agreement of the cycadeoids with the Trochodendraceæ, and in part with the magnolias, is in evidence far and wide from Jurassic, down into later Cretaceous times. It is too impressive to be without bearing on the origin of the angiosperms.

Much of this bettering of illustration and comparison has depended on more persistent and improved sectioning methods. Thus Mathiesen mentions that he found etching the Cape Dalton calcified materials with hydrochloric acid an advantage. This I also found an aid in clearing polished surfaces of calcified stems from the Isle of Wight. Also, silicified stems containing distinct amounts of residual carbon as in *Raumeria* and other cycads such as the *C. nigra* from Colorado, may be effectively etched with hydrofluoric acid where the requisite thinness and clearness is difficult to reach by the simple thin-section method. Followed by careful washing and covering, such sections supplement the gelatine pulls.

Upper Pressure Limit in the Explosive Chain Reaction between Hydrogen and Oxygen

WHEN the two pressure limits, between which the normally slow combination of hydrogen and oxygen, at, say, 540° C., becomes explosive, were first discovered, the existence of the lower limit was attributed to the deactivation of chain carriers at the wall of the vessel, and that of the upper limit to deactivation in the gas phase. Unless one or other of the deactivation processes is vigorous enough to balance a branching of the chains, explosion occurs. The theory of the lower limit has since been confirmed by detailed investigation, and shown to account for the facts more or less quantitatively. Theories which make the upper limit depend upon the vessel wall have also been suggested, but further experiments have shown that the assumption of some form of gas phase deactivation cannot be dispensed with.

Hitherto, no really quantitative theory about the detailed nature of this deactivation has been worked out. The first tentative idea was that it depended upon the mutual destruction of hydrogen peroxide molecules concerned in the propagation of the chain. The well-known theory of Haber that hydrogen atoms and hydroxyl radicles play the most important part in the chain naturally suggests that the deactivation might consist in the recombination of such atoms or radicles: for this a three-body collision would be advantageous.

The purpose of this note is to state that further experiments, shortly to be published, lend what seems to be practically conclusive support to the view that the upper limit is governed by ternary collisions in the gas phase. The particles which are deactivated or recombine in this process must be much more massive than pairs of hydrogen atoms.

The following simple theory accounts quantitatively for many of the facts about the upper limit. Let X and Y be two kinds of atom or molecule which collide in the course of a chain and let there be a certain probability that at such a collision the chain branches. If, however, any third molecule arrives while X and Y are associated together, then deactivation occurs. Equating rate of branching to rate of deactivation we have:

$$k[\mathrm{X}]\,[\mathrm{Y}] = Z_1\,[\mathrm{X}]\,[\mathrm{Y}]\,[\mathrm{H}_2] + Z_2\,[\mathrm{X}]\,[\mathrm{Y}]\,[\mathrm{O}_2] + \\ Z_3\,[\mathrm{X}]\,[\mathrm{Y}]\,[\mathrm{M}]$$

M representing an inert gas present. The *Z* factors are proportional to the collision frequencies of the complex X Y with hydrogen, oxygen or the inert gas respectively. From this it follows that at the limit $Z_1[H_2] + Z_2[O_2] + Z_3[M]$ is a constant. Experiment shows, in agreement with this, that at the limit in the absence of an inert gas, $[H_2] = C - b[O_2]$, and also that on addition of inert gas there is a linear decrease in the partial pressures of hydrogen and oxygen. The influence of helium is considerably greater than that of argon on account of its much greater speed, and consequently greater Z_3 value. Similarly, the constant b, which equals Z_2/Z_1, is much less than unity.

The value of Z can be shown to be proportional to $\sigma^2_{XYM} \Big/ \mu^{1/2}_{XYM}$ where $\mu = \frac{m_{XY} \cdot m_M}{m_{XY} + m_M}$, m_M, etc. being the molecular weights and σ_{XYM} the sum of the molecular diameters of the complex X Y and the colliding molecule M; similarly for Z_{H_2} and Z_{O_2}.

To allow the high speeds of hydrogen and of helium compared with oxygen and argon to have the influence in the calculation which experiment shows them to have in practice, the value of m_{XY} must not be too small. Thus X Y must be much heavier than a pair of hydrogen atoms. For the purposes of a preliminary calculation, we have assumed X Y to be an activated complex of H_2 and O_2, which has a finite probability of branching unless hit by a third molecule. Using the molecular diameters given in the table in Tolman's "Statistical Mechanics", we find that helium should have 1·77 times the effect of argon, while the experimental value is about 1·6. Moreover, the ratio of the Z values for hydrogen and oxygen gives the calculated value of the constant b as 0·39, compared with an experimental value of 0·325. Having regard to uncertainties in the molecular diameters, these agreements are very close, and show that the relative speeds of the different molecules principally determine the variation of the upper limit. Thus the theory of gas phase deactivation of fairly massive complexes in ternary collisions is strongly supported.

Structure and Division of Somatic Chromosomes in *Allium*

THREE divergent views have been expressed regarding the structure of chromosomes. Pfitzner in 1882 suggested that a chromosome is made up of a row of granules embedded in an achromatic or less chromatic matrix. About the same time, Baranetzky found a spiral structure in certain stages in the meiotic cycle of the chromosomes of *Tradescantia virginica*. Vejdovsky (1912) has termed this spiral the chromonema. The chromonema theory conceives of a continuous, filiform, spirally coiled chromatic element in an achromatic matrix. The alveolar theory foreshadowed by van Beneden and worked out by Grégoire and his pupils contemplates the homogeneous chromosomes of the metaphase becoming during the following stages a honey-combed structure by the appearance in it of numerous alveoles. The supporters of this view assume that a longitudinally aligned central series of alveoles would account for the origin of the split in each chromosome.

The exact nature of the behaviour of chromosomes both in mitosis and in meiosis, as well as their rôle in heredity, can be understood only if their real structure is known. A study of the structure of the chromosomes of *Allium* has been undertaken under the kind guidance of Prof. R. Ruggles Gates, with the view of solving some of these problems. A preliminary account of the results so far obtained by cytological observations and the use of wire models is given below.

(1) At the early metaphase each chromosome is seen to be composed of two spirally coiled chromonemata and the duality of this spiral has been observed in all stages of the mitotic cycle.

(2) The spiral is coiled in opposite directions in the two arms of the chromosome, the null point of the spiral being the attachment constriction of the chromosome.

(3) This form of double spiral permits of the separation of the chromosome into two by a simple uncoiling. This commences at the ends, as observed in *Allium*, but conceivably in some forms it may be initiated by the pull of the spindle fibres at the point of constriction.

(4) This unwinding causes rotation in the two arms of the chromosome; it may be possible that, as a result of this rotary motion in each arm of the chromosome, longitudinal cleavage is initiated in each chromonema at the metaphase stage.

(5) The separated chromonemata (daughter chromosomes), which now present a double spiral structure in each, remain parallel until they are finally pulled apart to the opposite poles of the spindle.

The doubleness of the anaphase chromosomes is clearly seen and the twisted appearance of these is due to slight loosening of the double spiral, which has been observed by Hedayetullah[1] in *Narcissus* and by Miss Perry[2] in *Galanthus*. The threads of this spiral retain their spiral structure in the subsequent stages of the mitotic cycle. The different appearances presented by the chromosomes in these stages are mainly due to the compact or loose nature of the double spiral. The dual threads remain closely associated together until their final separation at the next metaphase.

Further work on this subject is in progress and it is hoped that a detailed account may be published at a later date.

Synthesis of Protein by Green Plants

IN green plant tissues, the relation of protein synthesis to light has long presented puzzling features. It is known that many such tissues can synthesise protein in the dark if carbohydrate supply is abundant. Normally, however, protein accumulation in leaves appears to take place chiefly or solely in the light. In the case of an alga, *Chlorella*, Muenscher showed that approximately equal amounts of protein were accumulated if the algal cells were grown in either dark or light on a glucose medium containing nitrate. Muenscher's cultures were continued over a long time, and they simply show, therefore, that protein synthesis approaches the same *equilibrium* point in the dark as it does in the light.

Using the same strain of *Chlorella* as Muenscher (that of Hopkins and Wann), we have found that the alga grows and synthesises protein much more rapidly in the light than in the dark. Thus of a number of pure cultures (inoculated with the same number of cells and grown on a glucose medium containing ammonium nitrate), some were taken for analysis to represent the original condition, others were kept for three days (*a*) in the dark or (*b*) in continuous light. These yielded on analysis, as mgm. per culture, the following:

	Dry Weight	Total Nitrogen	Protein Nitrogen	Gain in Protein Nitrogen
Original	84·4	2·83	2·56	
Dark	112·1	3·42	3·05	0·49
Light	193·4	5·60	4·97	2·41

It thus appears that the *velocity* of protein synthesis is much greater (five times) in the light, though the final equilibrium is similar in either light or dark, if sufficient carbohydrate is available. This conclusion would also satisfactorily interpret the available data for the higher plants.

Insects and Micro-Climates

IT is well known that when water is exposed to dry air, evaporation takes place and the liquid becomes cooler than its surroundings; when a dish of water is placed in still air at 30° C., the temperature of the water is sometimes considerably lower than that of the air. The amount by which the water is cooler depends on the humidity of the air, for the lowering of the temperature is directly proportional to the rate of evaporation, which is governed by the saturation deficiency. In our experiments, when the air in the room has a humidity of 78 per cent, then the temperature of the water is 27·9° C., and when the humidity is 40 per cent, then the temperature is 22° C.

The temperature of the air immediately above the water in the dish has approximately the same temperature as the water. Experiments have shown that *Culex fatigans* is killed by an exposure to 41° C. for an hour, and it is suggested that its habit of resting in damp situations has enabled this insect to survive in countries where the shade temperature is frequently considerably above 41° C. Many insects which are found in these situations are probably attracted there by the lower temperature and not by the high humidity.

The large fall in temperature due to evaporation means that the conditions to which many insects are subjected are even more different from those measured by standard meteorological methods than is usually realised. In experiments with a number of different insects, we have shown that exposure to dry air is usually more rapidly fatal than exposure to moist at the same temperature. At first sight this would imply that, for any given temperature, the higher the humidity the more favourable the conditions for these insects; but it is possible that the effect may be the reverse, for the high atmospheric humidity will prevent evaporation and raise the temperature to which the insect is actually subjected. For example, in air at 35° C. with a relative humidity of 90 per cent, the temperature of the water would be 33° C. (assuming that 2·5 mm. saturation deficit gave a reduction of 1° C. which was the amount found in our experiments). If, however, the air was at 40° C. and had a relative humidity of 10 per cent—conditions which would prove rapidly fatal to many insects—then the water would only be at 20° C.

We should like to direct the attention of entomologists to these observations, in the hope that they will study the climatic conditions of the air in wells, over collections of water in rot-holes and in other places where insects are found resting.

Triphenylmethyl Derivative of Vitamin C

1 GM. of ascorbic acid (vitamin C) was dissolved in 5 c.c. of pyridine and 1·4 gm. triphenylchloromethane were added. After standing for two days at 30° C. the solution was diluted with chloroform, shaken out twice with water and dried with anhydrous sodium sulphate. The solution was evaporated *in vacuo*, the syrupy residue dissolved in a little benzene and precipitated with petrol. The precipitate was ground up in a mortar under 2 per cent acetic acid, dried, and reprecipitated from benzene as above.

Trityl-ascorbic acid is a white amorphous powder, easily soluble in chloroform, benzene, alcohol and alkali, insoluble in ether, practically insoluble in water and petrol. It begins to colour at 80° C. At 130° it melts with blackening and decomposition. Its specific rotation is + 30° (*c.* 3·0). Its percentage composition was carbon, 71·1 and hydrogen, 5·41; calculation for the formula $C_{25}H_{22}O_6$ gives carbon, 71·73 and hydrogen, 5·3.

The mono-acetone-ascorbic acid did not give a trityl derivative. The acetone-ascorbic acid and the triphenylchloromethane were recovered unchanged.

It follows that vitamin C contains a primary OH group, which is involved in mono-acetone-ascorbic acid in the formation of the isopropylidene group. Owing to the presence of a carboxy group, we may also conclude that vitamin C is not an aldehyde and the CO group is present as ketone.

Indophenol Reducing Capacity of Lemon Juice and its Fractions in Relation to Vitamin C Activity

MR. DANN[1] is labouring under a misapprehension in interpreting the results of my paper[2]. My figures show that if the reducing capacity of the various lemon juice fractions be interpreted in terms of fresh decitrated lemon juice, eighteen guinea-pigs receiving daily doses equivalent to 2 c.c. (reduction value 8–10 c.c.), eighteen receiving doses equivalent to 1·5 c.c. (reduction value 6–8 c.c.), thirty-six receiving doses equivalent to 1 c.c. (reduction value 4–6 c.c.), seventy-two animals in all (tested usually three in a group), died of apparently uncomplicated scurvy within 30–40 days. It need scarcely be stressed that young guinea-pigs do not vary in biological response to anything like this extent but *always* survive much longer than 30–40 days, even if they are not fully protected, on daily doses of 1–2 c.c. or even less of lemon juice. This fact invalidates Mr. Dann's inferences.

Vitamin C and Ascorbic Acid

Messrs. Birch, Harris, Ray and Dann have summed up in Nature of February 25 (p. 273) the arguments for believing that vitamin C and hexuronic (ascorbic) acid are identical. In the course of their observations they refer to "Ostermalt" as having been shown by their chemical method to contain an amount of ascorbic acid that should cause it to protect guinea-pigs from scurvy in a daily dose of 3·3 gm.; no figure was apparently available to the authors enabling them to compare this conclusion with an actual biological assay.

In further substantiation of the authors' views that ascorbic acid and vitamin C are identical, I may be permitted to state that Ostomalt, to which they presumably refer, as manufactured in these Laboratories for the last six years, contains a proportion of concentrated Californian orange juice ? The amount of this juice present in Ostomalt is such as to give the equivalent of half its own volume of fresh orange juice to the product. 3·3 gm. of Ostomalt occupy a volume of about 2·5 ml., and the figures given by Birch, Harris and Ray for the protective dose of orange juice are 1·2, 1·5, 1·9 ml. It will therefore be seen that the results obtained by their titration method are in good agreement with the equivalent of fresh orange juice present in the product.

A short while ago an independent laboratory, carrying out tests for an official body, found by biological assay that Ostomalt contained an amount of vitamin C that was "in very fair agreement with their [the manufacturers'] claim that the product contained antiscorbutic vitamin equivalent to half its volume of fresh orange juice".

It would therefore seem that the chemical estimation of the vitamin C present in this product, which is primarily a mixture of malt solids, concentrated orange juice, and cane sugar, with certain other vitamin supplements, is in substantial agreement with direct and indirect biological assays, affording further confirmation for the views of Birch, Harris, and Ray as to the identity of vitamin C and ascorbic acid.

An Inhibitor of the Antimony Trichloride Test for Vitamin A in Cod Liver Oil.

It has been shown[1] that traces of substances like furan, indol and skatol inhibit strongly the intensity of the absorption band of vitamin A with antimony trichloride at 620 mμ. In cod liver oil, there must be such an inhibitor, because after saponification a much stronger Carr and Price reaction is obtained with the unsaponifiable fraction.

Attempts to isolate this inhibitor by means of different soaps in various solvents; vacuum distillation; bromination and debromination; and cooling down to low temperature in different solvents, proved to be unsuccessful. However, I have succeeded in isolating it in the following way: Cod liver oil for medical purposes (pale yellow coloured) is saponified, acidified and the mixture of acids dissolved in five volumes of petroleum ether (b.p. 60°–80°). After drying with anhydrous sodium sulphate the solution is vigorously shaken up with 1/10 volume of diluted sulphuric acid (5 volumes of 96 per cent sulphuric acid + 2 volumes of water). The sulphuric acid layer contains the inhibitor and is poured out into a large volume of cold, saturated sodium sulphate solution. This mixture is extracted several times with petroleum ether. After evaporation of the solvent, the resulting oil is distilled and boils at 180°–210°/1–2 mm. This oil is dissolved in petroleum ether and again shaken out with sulphuric acid. The resulting oil, a pale yellow viscous substance, boiled at 203°/1 mm. From 1 litre of cod liver oil about 2½ c.c. was obtained.

The inhibiting power (measured by means of a Zeiss stuphometer with the *S* 61 filter) is four to five times as large as that of indol. The substance readily absorbs bromine and gives a strong orange yellow colour with tetranitromethane. The iodine value (Wijs) and bromine value (Kaufmann) depend on the time of reaction and excess of the reagent. Iodine values varied from 205 to 392, and bromine values from 166 to 364.

Molecular weight determination gave 332 (titrated as a mono-basic acid). Analysis gave as a formula $C_{21}H_{36}O_{3}$. Qualitative tests for sulphur and nitrogen (Lassaigne) were negative. Catalytic hydrogenation (platinum catalyst) showed absorption of about 4 atoms of hydrogen per molecule. The hydrogenated product has lost the inhibiting power, and gives no colour with tetranitromethane (bromine value after 5 minutes reaction = 0).

However, it may also be pointed out that the inhibiting power of a substance is not due to its unsaturation alone, because specially prepared, very pure, unsaturated fatty acids (oleic, linoleic acid) do not show any inhibiting power. Impure fatty acids (oxidised) give a red Carr and Price reaction; thus in presence of vitamin A there results a mixed colour, but no inhibition will be seen by spectroscopical research.

Dissociation of Nitrous Oxide in the Glow Discharge

In a recent paper, Kueck and Brewer[1] describe experiments made on the dissociation of nitrous oxide in the 'glow' discharge. Using a special disposition of electrodes which eliminates anode glow and positive column, they find, with fields of the order of 2,000 volts/cm., over a pressure range 2–5 mm., that the initial decomposition rate is practically independent of the initial pressure. Similar results for both nitrous oxide and ammonia have been described by Hinshelwood and Hutchinson[2], who, using a method which gives essentially the integrated dissociation throughout all parts of a normal glow discharge, state that for weak discharges the absolute amount of decomposition tends to be independent of the initial pressure. They observe, however, that for more intense discharges "the amount of decomposition becomes proportional to the pressure, i.e., the percentage decomposition is now independent of the initial pressure". This they term the "unimolecular state". Unfortunately, they give little data as to the potentials employed.

I have, for some time, carried out experiments on nitrous oxide under slightly different conditions, namely, in the high-frequency discharge (frequency approximately 100 kc.) in long tubes (*c.* 70 cm.) of 4 cm. diameter with external electrodes very close to the ends. Under these conditions, the glow is distributed almost uniformly throughout the gas. In the earlier experiments, damped high-frequency current from a spark oscillator was employed. Fields of average peak intensity ranging from 100 to 400 volts/cm. were applied, with initial pressures ranging from 0·1 to 3·0 mm., and a specially devised membrane gauge[3] enabled any one dissociation to be followed almost to completion.

The results were in substantial agreement with those of Hinshelwood and Hutchinson. At the lowest intensity of discharge, there was a definite tendency for the initial rate to vary little with the initial pressure, but at the highest potential difference employed there was a small pressure range in which the dissociation was sensibly unimolecular. The transition from one state to the other is shown strikingly by plotting the half-value period T, against the initial pressure p_0, for a given potential difference. For low potential difference, T increases rapidly with p_0, but the curve shows a slight inflection, which becomes more pronounced at higher potential differences and finally develops into a flat portion of curve parallel to the p_0 axis over an appreciable range of p_0. But even at points well removed from this unimolecular region, a given dissociation as a whole is found to be better described by a unimolecular law than by any other law of integral order, although the velocity constant is now pressure dependent.

In a further series of experiments (in collaboration with Mr. C. H. Noton) a valve oscillator was used, current measurements were made, and an improved discharge tube and gauge allowed the dissociation to be followed in greater detail. Measurements were made well away from the unimolecular region. It was found that for a brief period (3–4 sec.) after initiation, the dissociation rate increased, rapidly attained a maximum, and then proceeded 'normally'. The current varied in a similar manner, reaching maximum shortly after $(dp/dt)_{\max.}$. A number of considerations militate against its being ascribed to possible selective adsorption on the walls in the initial stages, and the effect appears to be real. A similar and much larger effect has also been observed with nitrogen pentoxide. Further experiments are in progress and are being extended to ammonia. It is hoped to publish shortly details of the experiments already made.

Relative Intensity of Spectral Lines in Indium and Gallium

DURING 1932, work has been carried on in this laboratory on the measurement of the relative intensity of spectral lines in the above elements. The amount of material available was very limited, consisting of a small quantity of metallic indium and a little gallium chloride, both kindly supplied by Prof. Fawsitt, of the Inorganic Chemistry Department of this University. All this material has now been used up, and thus the results are published at this stage.

Results are given for the doublet $2p_{3/2}-2s_{1/2}$ and $2p_{1/2}-2s_{1/2}$ for each element. The wave-lengths of these lines are 4511 A. and 4102 A. respectively for indium and 4172 A. and 4033 A. respectively for gallium. Measurements of other doublets of the same series had not been successful by the time the material had all been used up.

The photographic methods introduced by Prof. Ornstein were followed fairly closely. The spectra were produced in an arc with silver-tipped copper poles, which gave a clear spectrum in the required regions. In the case of indium, a button of the metal alloyed with lead was placed on the lower pole, while for gallium the chloride was packed into a hole drilled in the lower pole. The potential applied to the arc was in one plate 100 volts and in the others 250 volts, while the arc current was 3–4 amp. A set of density marks, taken with a small incandescent lamp calibrated photographically by means of a standard lamp, was put on each plate. A reducer was used to divide each spectrum into two parts so that two sets of readings might be obtained from each spectrum. These two sets agreed within experimental error. The exposure time for the arcs varied, and was not always the same as that for the density marks, but there is no corresponding variation in the results.

When an arc was taken using pure indium, a reversal effect was obtained. To investigate the effect of this, alloys of lead and indium were made up, containing different proportions of the two metals, varying from 1 In : 10 Pb to 1 In : 500 Pb, and used in different plates. These alloys were prepared by melting the lead and indium together in a crucible under tallow to prevent oxidation. The mean results obtained with different alloys showed no regular variation, so that apparently any reversal effect is negligible at these concentrations. With the same object, some of the gallium arcs were taken with pure gallium chloride and others with a mixture of approximately equal parts of the chlorides of zinc and gallium. Both gave the same results within experimental error.

The results for indium are given below. The first column gives the proportions by weight of indium to lead in the alloy used in the plate. The intensity ratio given in the third column is that of the line of longer wave-length. The ratio a_1^2/a_2^2 is obtained from I_1/I_2 by multiplying the factor $(\lambda_1/\lambda_2)^4$, a_1 and a_2 being the amplitudes of the virtual oscillators given by the equation $I = a^2v^4$. The last row in the table gives the mean of all the results for different plates and concentrations.

In./Pb.	No. of Readings.	Mean I_1/I_2	Mean a_1^2/a_2^2	Mean error in I_1/I_2
1/10	5	1·66	2·42	0·11
1/33	3	1·51	2·21	0·06
1/33	3	1·73	2·53	0·09
1/33	7	1·64	2·39	0·05
1/100	4	1·47	2·15	0·06
1/500	7	1·61	2·35	0·04
	29	1·62	2·35	0·09

The corresponding results for gallium are given below. The last row again gives the mean of all the results.

No. of Readings.	Mean I_1/I_2	Mean A_1^2/A_2^2	Mean error in I_1/I_2
8	1·36	1·55	0·07
8	1·36	1·55	0·07
16	1·36	1·55	0·07

The mean values of a_1^2/a_2^2 obtained for this pair of lines for indium and gallium, namely 2·35 and 1·55 respectively, may be compared with the value 2·58 obtained by Prof. Vonwiller[1] for the corresponding pair for thallium.

In conclusion, I wish to thank Prof. Vonwiller, who suggested the work, for his continued help and advice.

Absorption Bands of Iodine Vapour at High Temperatures

I HAVE investigated the absorption of iodine vapour in a tube of 26 cm. length at temperatures above 800° C. over the region 2900–5000 A. and have observed the appearance of a continuous absorption band with a sharp limit at 3425 A. on the long wave side. With increasing temperature the intensity of this band increases and at 900° C. a new absorption band appears with the long wave limit at 3252 A. At about 1050° C. both bands extending from 3425 A. to 3000 A. change in appearance, showing on the continuous background many close bands. These are extremely diffuse and it was impossible to decide whether they are genuine band heads or due to fluctuations of intensity in the continuous spectrum.

The table below gives the temperature t and the vapour pressure p at which each kind of spectrum appears.

Limit of band.	Broad continuous band appears at		Narrow bands appear at	
	t	p in mm.Hg.	t	p in mm.Hg.
3425 A.	775°	80	1050°	760
3252 A.	885°	760	1050°	760

If the vapour has the temperature 1050° C., the broad continuous band at 3252 A. appears first at a pressure of 150 mm. mercury. Similar experiments were also made with a shorter absorption tube of 13 cm. length and it was found that the length of the tube does not affect the appearance.

The following are peculiar features of these absorption bands: (*a*) an abrupt limit on the red side which in the region investigated is independent of the temperature between 800° and 1050° C; (*b*) the maximum of the absorption lies close to the red edge of the band, namely, at 3425 A.; another less prominent maximum lies at 3252 A.; (*c*) the bands extend down to about 3000 A.

Oldenberg[1], investigating the influence of foreign gases on ultra-violet fluorescence of the iodine vapour, observed these bands in emission. He found that with increasing pressure of foreign gas the continuous band at 3460 A. first increases and then spreads into many narrow diffuse bands. The same phenomenon was observed by Cario and Oldenberg[2] in electric discharges through narrow capillary tubes in iodine vapour and by E. Hirschlaff[3] in fluorescing vapour at high temperatures. The narrow absorption bands show an exact agreement with those measured by Oldenberg between 3252 A. and 3000 A.; in the region 3425–3252 A., however, the bands quoted by Oldenberg were not all found and those actually observed show an irregular increase of $\Delta\nu$ with the wave-length.

The appearance of these bands in the absorption spectrum seems to contradict Oldenberg's suggestion ascribing their origin to the recombination of iodine ions $I^+ + I^- = I_2 + h\nu$ (*Ionenvereinigungsleuchten*).

In connexion with the observed absorption band limit at 3425 A. (800°–1050° C.) it is of interest to note that according to Oldenberg's observation in fluorescence (20° C.), the band limit appears at 3460 A., whereas Hirschlaff finds it at 3439 A. also in fluorescence (640° C.).

Neutrons

I HAVE obtained the following result, from a unified field theory. Two particles, of charges e, E, and masses m, M exert on each other, apart from the usual electrostatic force, also a 'gravitational' repulsion with a potential

$$\frac{e^2E^2}{4mc^2}\,\frac{1}{r^2}$$

if $M >> m$.

If this result is correct, it could account for the existence of neutrons. An electron and a proton are held together in a neutron by combined attractive and repulsive forces which are in statical equilibrium. The size of a neutron is thus $r \simeq 1{\cdot}4 \times 10^{-13}$ cm., and the binding energy is $mc^2 \sim 5 \times 10^5$ electron-volts.

Chadwick's values for the size and binding energy of a neutron are 10^{-12}–10^{-13} cm. and 10^6 to 2×10^6 electron-volts.

Preservation of Fossil Bones

REFERRING to the note in NATURE of January 28, p. 129, I have found that the safest and simplest method of hardening permanently and without discoloration the tusk and osseous fragments of the great Mammalia (mammoth and rhinoceros) recently found in the west of Scotland is repeatedly to baste the pieces with a strong solution of gum Dammar. This should be done after the object has become rather dry but before any warping occurs.

The method of treatment will, however, depend upon the condition of the relics. The Scottish pieces which I have handled are now exhibited in Kelvingrove Museum, Glasgow, and were all found in a very wet and spongy condition, 15–25 ft. under grass-level and in the laminated gravels of the old raised terrace of the Kelvin River, some eight miles east of Glasgow, at about 170 ft. O.D.

Had the pieces been allowed to remain without treatment, disintegration would now have been complete; with an incalculable loss to science.

Research Items

Ancient and Modern Man. In opening a discussion on man's kinship with the primates at the Royal Anthropological Institute in November last (*Man*, No. 9, 1933), Dr. S. Zuckerman offered the suggestion that the existing classification of man is irrational, preventing a convincing evolutionary interpretation of the remains of fossil man available for study. Dr. Zuckerman reviews the evidence on which he bases his suggestion in the *Eugenics Review*, vol. 24, No. 4, and arrives at the tentative conclusion that archaic types and modern man fall into two easily definable groups, the sub-family Palæanthropidæ comprising such forms as *Pithecanthropus*, Peking man, and Neanderthal man; and the sub-family Neanthropidæ consisting of types like modern man and the men of the upper palæolithic. Generic status has been assigned to *Sinanthropus*, yet taking the ten Neanderthal skulls selected for contrast by Prof. Davidson Black, they show intra-specific differences of linear dimensions often greater than those regarded as generic differences in the family Hominidæ. Again, in the main distinguishing feature of Neanderthal skulls, the small flattened sagittal area, *Sinanthropus* corresponds not only to Neanderthal man, but also to Rhodesian man and *Pithecanthropus*. Differences in the vertical planes in which certain breadth measurements of the brain-case fall have been taken as differentiating *Pithecanthropus* and *Sinanthropus*, yet as important a difference in one of the breadth measurements differentiates all Neanderthal men from modern man; but here it is regarded as specific only. The difficulties which arise from the unequal significance attached to the peculiarities of Neanderthal man, *Sinanthropus* and *Pithecanthropus*, point to one of two conclusions—either *Sinanthropus* should be included in the genus *Pithecanthropus* or the accepted classification of all extinct Hominidæ should be revised.

'Iberomarusian'. In *L'Anthropologie* (T. 42, Nos. 5–6) MM. E. G. Gobert and H. Vaufrey discuss the application of the term 'Iberomarusian' coined by A. Barbin (1869–1932) to distinguish an industry discovered by him in the cave of La Mouillah, near Marnia (Oran). This culture he regarded as closely related to the upper palæolithic of south-east Spain, described by Siret. The most characteristic feature of the culture is its microlithic industry, though it has been regarded as distinctively palæolithic. Other Iberomarusian sites have been identified in eastern Morocco, Oran, Algiers and Constantine. A distribution map published in 1914 shows that Capsian and Iberomarusian are mutually exclusive, the former being confined to the southern Tunisian area and adjacent province of Constantine, while the latter belongs to the littoral area of the tells. The authors now describe two sites which mark the extremes of the Iberomarusian culture in east and west. These are Ouchtata (Tunisia) and El-Hank and Aïn Rahmane (Casablanca). The description of the finds on these sites establishes the character of the culture with greater precision, while the El-Hank site indicates the close relation of the Iberomarusian with the underlying Aterian, which is a late survival (also found elsewhere in Africa) of a technique of Mousterian origin. Tentatively it is suggested that the Iberomarusian is the littoral facies of the continental Capsian and that in the steppe region the typical Capsian overwhelmed and took the place of the Aterian, which on the littoral lies at the base of the Iberomarusian. This last is mesolithic rather than palæolithic. But even if the Iberomarusians and Capsians possessed industries of widely different facies, they were nevertheless of one and the same race, that of Mechta el-Arbi. The evidence being against the African affinities of the upper palæolithic of south-east Spain, 'Iberomarusian' might possibly be replaced by 'Oranian'.

Spread of Eskimo in Greenland. It is rare in modern times to find an extension of the area occupied by primitive people. There are abundant signs that in the past all the ice-free border of East Greenland was occupied by wandering Eskimo but the last seen on the north-east coast were on Clavering Island in 1823. In 1894 the Danes founded the Eskimo settlement of Angmagssalik in the south-east and in recent years have been successfully promoting further settlement. In a lecture to the Royal Geographical Society on February 6, Capt. E. Mikkelsen described some of these efforts and discussed the habitability of the coast, especially the Boisseville Coast between Kangerdluksuak and Scoresby Sound. A new colony of 85 Greenlanders, transferred from Angmagssalik, was established at Scoresby Sound in 1924. This colony flourished and now numbers 150. Conditions in the vicinity point to the possibility of its extension. Seals, walrus, narwhals, foxes, bears and birds are abundant. The musk-ox also occurs in fair numbers but these are protected at present. It is essential, however, if the colonies are to thrive, that the seal and walrus shall be protected from European hunters not only along that coast but also farther to the north, whence the ice-floes come south with the seals. The Boisseville coast is less attractive but the number of bears show that seals are abundant. Eskimo have already used this coast in the past and it is the aim of the Danes to establish along it a line of contact between the Scoresby Sound colonies and Angmagssalik.

Abnormal Chitons. Iw. Taki (*Mem. Coll. Sci.*, Kyoto Imp. Univ., Ser. B, vol. 8, No. 1, 1932) records eight specimens of Japanese chitons with less than the usual number (eight) of shell-plates. Examples are described in which reduction to five, six or seven plates has occurred, with subsequent regulation of form among them, including cases in which a shell-plate partly atrophied has fused with other plates. Specimens with a reduced number of shell-plates tend to have a shorter body-length than normal. The author brings together previous records of hypomeric and coalesced shell-plates—35 with seven plates, 9 with six plates, 2 with five and 2 with three plates. There is no case recorded in which the number of plates exceeds eight.

Bast-Sap. Prof. H. H. Dixon (*Sci. Proc. Roy. Dub. Soc.*, 20 (N.S.), 487–494) has described experiments which, it is claimed, elucidate the path and mechanism of translocation in plants. It is now suggested that the sieve tubes can permit a mass flow of solution. Experiments are described which show that under external pressures of 3 atmospheres, a solution introduced into the phloem moved at a rate of 7–8 cm. per hour. An incision into the phloem, without penetrating the xylem, frequently causes, especially in angiosperms, an exudation of a minute amount of liquid (0·1–0·2 c.c. from a 1 mm. slit in 30 min.) which contains organic matter (up to 12 per cent sugar). This mechanism of phloem exudation, which is now attracting considerable attention, is supposed to reveal the composition of the moving fluid and also to demonstrate the reality of mass flow. The osmotic pressure of the exudate varied from 13 to 35 atmospheres. Experiments on *Fraxinus excelsior* show that the sap from a higher level is always more concentrated than from a lower. This difference (maintained chiefly by the supply of carbohydrates at a high level and their removal at a lower) causes the flow along the sieve tubes. It is suggested that the theory offers adequate explanation for other recent results on ringing experiments.

Uses of Rice Grass. The history of the remarkable polyploid plant *Spartina Townsendii* has recently been described by J. Bryce ("The Economic Possibilities of Rice Grass", *J. Roy. Soc. Arts*, 81, No. 4176, Dec. 2, 1932) who shows how its habit of growth is specially suitable for use in land reclamation and the prevention of coast erosion. Many striking instances of its wonderful power of colonisation are given, and experiments on the best methods for the utilisation of this power are described. In Holland, where the Kreekrak Polder was rising at the rate of a foot in five years, *Spartina* caused the level to rise nearly five feet in a similar time. Rice grass is also a palatable food for farm animals, especially sheep, and large yields of produce can be obtained. It can be grown in districts where salt abounds, either on the seashore or in the neighbourhood of artesian wells the waters of which are heavily charged with saline matter.

Phylogeny of Ammonites. A monograph on the Lower Triassic ammonites of North America (U.S. Geol. Surv. Prof. Paper 167, 1932, pp. 199, pls. 81) by the late J. Perrin Smith is the last of a series of five works on Carboniferous, Permian and Triassic ammonoids published from 1903 onwards. The Lower Triassic ammonites of North America have been found in Idaho, California, Nevada and Utah, and comprise 117 species belonging to 32 genera. Only three of the genera are peculiar to North America and it is probable that these will eventually be found elsewhere. Three families, the Xenodiscidæ, Meekoceratidæ and Hungaritidæ, are almost certainly immigrants from the Indian region, while the Proноritidæ and Thalassoceratidæ are probably native to the American region. *Tirolites* is an immigrant from the Mediterranean region. The Celtitidæ appear in America, on one side, and in Albania on the other, and probably originated in the Arctic province. Of the five zones which have been recognised in the Lower Trias, only three are found in North America, the zones of *Meekoceras*, *Tirolites* and *Columbites*. The systematic part of the work is fundamentally phylogenetic and is based on the stratigraphical succession of adult forms, and on the evidence of ontogeny. The author is convinced that the late Palæozoic and early Mesozoic ammonoids repeat in their ontogeny their ancestral history with a fair degree of exactness, for they had not been greatly affected by unequal acceleration of development and scarcely at all by retardation or arrest of development. In the Jurassic and Cretaceous Ammonites recapitulation is not so distinct, because the disturbing factors (acceleration, retardation, and the development of cænogenetic characters) have combined to obscure the record. By the application of these methods the author traces the various genera of Lower Triassic ammonites back to their Palæozoic ancestors, but for the details of this phylogenetic study the work itself must be consulted.

Lowering of the Japan Sea Floor. Prof. H. Tsuya has described some pebbles recently brought up from the bed of the Japan Sea (*Earthq. Res. Inst. Bull.*, vol. 10, pp. 864–875; 1932). They were collected at various points on a submarine ridge, the Yamato Bank, that runs northwards from the south-west coast of Japan, and at depths of 1,500–2,000 ft. The pebbles are rounded or subangular, and vary in size from mere sand-grains to more than 20 in. in length. All of them have the general petrographic characters common to their respective rock-types now exposed in the Japanese islands. It is improbable, from their wide distribution, that they are ballast dropped from passing ships, and, from the size of some of them, that they were transported by currents so far from the present shores. There remains the alternative that the sea-floor on which the pebbles lay was, in recent geological time, either a land-surface or a shallow sea near the shore, and the author directs attention to papers by Dr. H. Yabe (*Bull. Imp. Acad.*, vol. 5, pp. 167–169, 430–433; 1929), in which are described two submarine shelves round the coast of Japan, furrowed by valleys that are continuations of those on the present land. From the depth of the margin of the lower shelf, Dr. Yabe infers that the Japanese islands were at no very distant date joined to the continent and that they have since then subsided by not less than 2,360 ft.

Further Calculations of Electron Scattering by Atoms. In a recent paper (*Proc. Roy. Soc.*, Jan.) Massey and Mohr amplify their previous work on the scattering of electrons by atoms. The wave-mechanical problem involves in general the distortion of the incident electron wave by the atomic field, exchange of electrons between the atoms and the incident beam, the disturbance of the atomic field, and the distortion of the scattered wave by the new atomic field. The distortion of the scattered wave might be expected to be large in the case of inelastic collisions as the spread of the atomic field and the wave-length of the electron are both increased by the collision, and the present paper represents an improvement on previous work in that this distortion is included as well as the effect of exchange of electrons. The calculations have been carried out for the elastic scattering in hydrogen and helium and for electrons which have excited the 2^1P and 2^3P states of helium. The new curves for the atomic cross-sections do not differ very significantly from the old, and at low velocities the theory predicts too large a cross-section. This behaviour is probably due to the neglect of the disturbance of the atomic wave functions by the incident electrons. The theory applied to inelastic scattering by heavy atoms shows that the angular distribution of scattering is similar to that for elastic collisions, except at low velocities and large angles, and this is in accord with observation.

Radioactivity of some Rare Earth Elements. The radioactivity of samarium has been reported by Hevesy and Pahl (NATURE, 130, 846, Dec. 3, 1932) and this observation has been confirmed by Libby and

Latimer (*J. Amer. Chem. Soc.*, Jan.), who have also found the elements lanthanum and neodymium to be radioactive. The activities of lanthanum and neodymium are not appreciably screened by 0·07 mm. of aluminium, whereas that of samarium is largely, if not completely, screened, indicating that the activities of the former are mainly of the β-type whilst that of samarium is due to α-rays. Two different samples of neodymium, one sulphate and the other oxalate, showed a molar activity about 2·5 times that of potassium; the lanthanum activity was eight times that of potassium and the samarium about three times. Very pure gadolinium sulphate gave a negative result. It is considered that the radioactivity of the three rare earth elements is due to the presence of unstable isotopes, but the possibility of the presence of actinium as an impurity in the lanthanum and neodymium samples has not been excluded.

Steam-Jet Operated Air Ejectors. Steam jets have long been used for increasing the draught through boiler furnaces and in connexion with vacuum brakes on trains, and in 1902 Sir Charles Parsons introduced his 'vacuum augmenter' for increasing the vacuum in a condenser of a turbine plant. Since then, single-stage and two-stage ejectors have come into common use in power stations. The theory of the appliance is not a simple one and the success attained with various types has been mainly due to prolonged experimental investigations. Some of these investigations have been carried out in engineering laboratories. One such inquiry was described by Dr. A. H. Church in a paper published in 1927 in the *Journal* of the Royal Technical College, Glasgow, while on February 17, Mr. F. R. B. Watson in a paper read to the Institution of Mechanical Engineers dealt with a recent investigation made in the engineering laboratory in the University of Bristol. His paper was entitled "The Production of a Vacuum in an Air Tank by Means of a Steam Jet". The objects of his investigation included the study of the effect of the distance from the steam nozzle to the diffuser, the explanation of the action of the parallel throat in an ejector and the determination of the ratio of steam to air at different vacua and under different initial steam pressures. A description of the plant used was given and the paper was illustrated with photographs, curves and tables. The paper is printed at length in *Engineering* for February 24 and March 3, the latter issue also containing a report of the valuable discussion which followed the reading of the paper.

Astronomical Topics

The Reinmuth Planet, 1932 *HA*. This is the planet that can approach the earth within 3 million miles, and that actually came within 6 million miles last May. Dr. G. Stracke has published a very careful discussion of its orbit (*Astr. Nach.*, No. 5919) including the effect of planetary perturbations. Unfortunately, the accurate observations cover a range of only 18 days, April 27–May 15. The discovery plates on April 24 had such long trails that they could not be measured with exactness. The planet was photographed at Johannesburg on May 7; combination of this position with northern ones indicated a parallactic shift of about 100″, giving a good determination of the distance from the earth. The following are Dr. Stracke's elements:

Epoch 1932 Apr. 25·0 U.T.			q	0·644597
M	319° 59′ 1·60″		e	0·5662417
ω	284° 51′ 48·73″	1932·0	a	1·4860743
☊	35° 50′ 19·59″		Period	1·8116 years
i	6° 25′ 10·85″		n	1958·6005″
			T	1932 July 7·5

The period just exceeds that of Eros, 1·761 years; Eros has still the shortest known period among the minor planets. But both Eros and *HA* have shorter periods than Mars (1·881 years). *HA* makes a still closer approach to the orbit of Venus than to that of the earth, so it is subject to considerable perturbations from these planets.

Dr. Stracke fears that there may be great difficulty in recovering *HA*; but efforts will doubtless be made in the spring of 1934, though its distance from the earth will be considerably greater than in 1932. It will not receive a permanent number or a name until it is recovered, as the present range of observations is too short for this purpose.

Annuaire Astronomique Camille Flammarion, 1933. This attractive handbook, published annually by the Observatory of Juvisy, contains the usual calendar information with diagrams of the planetary paths among the stars, and descriptive articles about them. The article on Pluto states that "it is certainly not greater than the Earth, or even than Mars". The last four words cannot be taken as certain; many of the estimates of its mass exceed that of Mars.

In the diagram of the tracks of future solar eclipses that of 1945, total in Norway, has been inserted; it was accidentally omitted last year. The table of elements of periodic comets is carefully kept up to date by M. F. Baldet. It includes the observations of the first half of 1932. The stellar tables include explanations of the spectral types, and details of magnitude, distance and motion. There are light-curves of some variable stars and details of novæ. The list of the latter includes 20 somewhat doubtful ones before 1572 and 41 certain ones observed since that date; 31 of the latter are between 1892 and 1925 showing that the rate is about one a year.

A cryptic sentence on page 185 seems to need revision: enumerating the various motions of the earth, it concludes: "Enfin, un quatorzième mouvement . . . a été découvert en 1916: le déplacement . . . du système sidéral tout entier, . . . à la vitesse de 600 km./sec., vers . . . la constellation du Capricorne."

The Observer's Handbook for 1933. This volume, published by the Royal Astronomical Society of Canada, contains, besides the usual calendar matter, diagrams of the paths of the planets through the stars, with some details about Pluto (the earliest photograph of which was taken in 1914, and not 1919 as stated). There are useful notes on the phenomena of each month and a table giving particulars of the positions, spectral type, distance, absolute magnitude and motion of the 260 brightest stars: another table does the same for the 35 stars nearest to the sun. A few stars occur in both tables. There is also a list of occultations of stars by the moon visible at Ottawa in 1933.

Virus Diseases[*]

THE term 'virus', formerly used in a much wider sense, has recently been given a special and restricted application. Viruses are distinguished from such long-recognised agents of infection as bacteria by their small dimensions, putting many of them beyond the limit of clear visibility by the highest powers of the microscope, and allowing them to pass through filters fine enough to retain the smallest ordinary bacteria; and by the fact that they cannot be cultivated on ordinary, non-living media. The work of Pasteur and Koch initiated an epoch of investigation on the relation of visible bacteria to different infections, so that the first clear recognition of the existence of ultramicroscopic and filterable infective agents came only in the last decade of the nineteenth century, and the present century has seen the rapid progress of investigations on their nature. The viruses first recognised—those of mosaic tobacco disease and the foot-and-mouth disease—are still far beyond the range of the most advanced microscopical methods, and, if studied by themselves, might still be regarded as living contagious principles in solution. A large number of diseases of man, animals and plants are now known to be due to infection by viruses, and methods now available have shown that the infective units of the different recognised viruses cover a wide range of dimensions.

Ordinary bacterial filters only indicate that the sizes of the infective units of viruses are below a certain maximum. Ordinary microscopical methods may show that the particles of a particular virus are beyond the range of resolution, or that it contains particles which can be brought just into the range of visibility (about $0 \cdot 2\ \mu$) when loaded with a dye. Neither of these methods, however, enables the natural sizes of the units of different viruses to be determined for comparison.

Conventional microscopical methods revealed the association between infection with certain viruses and the appearance in the infected cells of the relatively large structures termed 'inclusion bodies'. These could not represent the virus in the form in which it passes a bacteriological filter. In 1904, however, Borrel described extremely minute bodies in suitably stained films from the juice of tissues infected with fowl-pox, and similar 'elementary corpuscles' were later found in material from vaccinia (by Paschen) and from *Molluscum contagiosum*. The important discovery was made in recent years (Goodpasture) that the large 'inclusion bodies' consist of 'elementary corpuscles' closely packed in a structureless matrix, and that a single washed inclusion body will transmit a virus infection. The evidence for identification of the elementary corpuscles as the organisms of these viruses has been strengthened by their agglutination with sera from animals immune to the corresponding virus (Ledingham).

In the absence of any possibility of testing their identity with the virus by artificial culture, there remained that of comparing the sizes of fresh, unstained elementary corpuscles from different viruses, as measured on photographs of critical microscopic images, obtained with ultra-violet rays of a suitable wave-length (Barnard), with the sizes of the infective units of the corresponding viruses, as measured by differential filtration through graded collodion membranes, of which the effective pore dimensions could be determined with sufficient accuracy (Elford). The comparison of the measurements of visible corpuscles, on one hand, and infective units on the other, has now been completed in the case of several viruses, and has shown a correspondence so satisfactory as to leave no room for doubt that the elementary corpuscles are the organisms of these viruses.

Filtration measurements of the infective units of other viruses, however, show that they are much too small to be brought within the range of any microscopical method which can be foreseen. In the case of the virus of foot-and-mouth disease, the units appear to have a diameter as small as about $10\ m\mu$, only about twice that of the molecule of oxyhæmoglobin. The difficulty of regarding such minute particles as self-propagating organisms has given rise to the suggestion that they are toxic principles, reproduced by the perverted metabolism of cells which they infect. A similar suggestion has been made to account for the reproduction of the virus-like lysins or bacteriophages which infect bacteria. In both cases, however, such a theory seems to be incompatible with recent evidence dealing with specific immunity to such viruses.

Specific treatment of viruses is still limited to the production or re-inforcement of a naturally acquired immunity. Recent success in that direction with dog-distemper (Laidlaw and Dunkin) has aroused in some minds a hope of similar success with a human disease, such as influenza. The analogy fails, unfortunately, through lack of an animal species in which the influenza virus can be propagated and made the subject of deliberate experiment, and of evidence of a strong and lasting immunity to its attack. The facts, however, that methods for the exact study of viruses are only now becoming available, and that knowledge of their properties is of recent and rapid growth, justifies a general hope of much wider success in dealing with the diseases which they produce.

---

[*] Substance of a lecture entitled "Ultramicroscopic Organisms and the Troubles which they cause", delivered by Sir Henry Dale, Sec. R.S., at Bedford College, London, on March 1.

Geology in Great Britain

THE "Summary of Progress" of the Geological Survey of Great Britain for 1930 has been issued in the three parts that have now become customary, the first[1] being devoted to the annual reports of the Geological Survey Board and of the Director and to the routine work carried out during the year under review, while the others contain papers on subjects of special interest. Forty-four maps were published with seven English and three Scottish memoirs, some of which have already been noticed in our columns (NATURE, vol. 127, 574, April 11, 1931).

Of the Scottish memoirs, that dealing with Ardnamurchan deserves special mention. It is a work of unrivalled geological interest that will always rank as one of the greatest contributions to the literature of Tertiary igneous activity in the British Isles. This memoir has already been individually reviewed (NATURE, 128, 619, Oct. 10, 1931). It is noteworthy that work has been resumed in the Ardnamurchan-Moidart area of the West Highland district. The survey of Unst has been completed and a summary report accompanied by a geological map is supplied by H. H. Read.

An important statement in the report of the Survey petrographer refers to the Cheviot granite: "It has been established beyond reasonable doubt that the normal Cheviot granite is a soda-rich granophyric granite almost devoid of ferromagnesian constituents, and that the so-called augite-granite owes its unusual characters to the incomplete assimilation of basic material derived from the andesitic lavas".

In Part 2[2] there are five papers on various aspects of Carboniferous geology and palæontology. Sir John Flett contributes a stimulating paper on a teschenite sill in Fife, and W. Q. Kennedy gives a critical discussion of the parent magma of the British Tertiary Province. The results of a gravitational survey over a region of magnetic anomaly in Leicestershire are recorded by W. F. P. McLintock and J. Phemister. In Part 3[3] these authors also describe a magnetic survey over the Lornty Dyke in Perthshire, while A. F. Hallimond deals with a similar survey over the Pentland Fault near Portobello. Stanley Smith continues his invaluable work on corals, describing here his investigation of certain Upper Carboniferous species from Glamorganshire. The zonal sequence of the non-marine lamellibranchs of the Upper Carboniferous of Yorkshire is dealt with by D. A. Wray and A. E. Trueman.

Discussing the correlation of the British and French Upper Coal Measures, R. Crookall concludes that our highest Coal Measures are the equivalent of the Upper Westphalian of the Continent. Bernard Smith gives records of a suite of borings through the glacial drifts of the northern part of the Isle of Man. Sir John Flett returns to the problems of differentiation presented by teschenite-picrite sills, dealing here with a sill encountered in a boring at Blackness on the south shore of the Firth of Forth. The petrography and stratigraphical position (Caradocian) of the keratophyric lavas of the Tweed valley in Peeblesshire are described by R. J. A. Eckford, M. Richie and D. Balsillie. In an important paper on a carbonate rock associated with cromaltite in the Loch Borrolan laccolith, J. Phemister reaches the conclusion that the so-called limestone is not of sedimentary origin, but represents a carbonated ultrabasic rock; the demonstration removes the only piece of direct evidence which has been advanced in favour of assimilation of limestone in this alkali intrusion.

The memoir on the Whitehaven and Workington district[4] covers part of the western fringe of the Lake District and the lowland mining and agricultural areas extending to the Solway Firth and the Irish Sea (Sheet 28). The region owes its economic importance to its wealth of coal and iron ore lying close to the seaboard. The memoir is the first complete description of the area to be published, and in view of the great variety of geological formations and tectonic episodes, it constitutes a noteworthy contribution to British geology. Many problems of general interest are discussed. The Skiddaw slates are found to have closer analogies with the Levis shales of Quebec than with their equivalents in Wales and Shropshire. The Ennerdale granophyre is shown to be a stock rather than a laccolith and to be of probably Caledonian age. Seven chapters are devoted to the Carboniferous formations. A very large number of shaft and boring sections have been examined and surface mapping has been supplemented on an unusual scale by observations underground. The red Permo-Triassic beds present many fascinating problems. There is a remarkably full sequence of glacial deposits, three episodes, each comprising an advance and retreat of the ice, having been established. The second glaciation, due to combined Lake District and Scottish ice, has left a widespread record of powerful erosion, ground moraine and drumlins, eskers, kames, deltas and overflow channels. Other chapters deal with recent deposits and economic products, and special mention must be made of a masterly chapter on the structure of the district.

The Brampton district[5], portrayed on Sheet 18, is an attractive area stretching east from Carlisle to near Haltwhistle, which includes parts of the Alston block, Tyne gap, Edenside and the Carlisle plain. The rugged crags of the Whin Sill, surmounted eastward from Greenhead by the Roman Wall, are of interest both to geologists and archæologists. The Carboniferous rocks naturally claim most attention and they are of special importance in forming a link between Northumberland and West Cumberland. Although the Midgeholm coalfield is now almost exhausted, appreciable reserves of the Little Limestone coal still exist. A noteworthy account of the rhythmic cycle of deposition characteristic of the Yoredale Series is given. In the New Red Sandstone Series of the western half of the district the only mineral of value is the gypsum used for plaster making. Glacial drifts mask the outcrops of the solid rocks over widespread stretches, and the chapters that deal with the waxing and waning of the glaciers and with the development of the river systems are of more than usual interest.

The Manchester memoir[6] is descriptive of Sheet 85, which covers an area extending west to Tyldesley, north to Bolton, Bury and Rochdale, and east to Oldham and Hyde at the foot of the Pennines. It thus embraces much of the highly industrialised area of South Lancashire. Although the region has been heavily exploited in the past, there are still considerable resources of coal within easy reach. Apart from chapters on the Permo-Triassic rocks, tectonics and glacial geology, the memoir is almost wholly devoted to the stratigraphy, palæontology, structure, and economics of the Coal Measures. Investigation of fossil bands which mark important horizons has been extended over the whole field, and wherever exposures are available has afforded a more exact correlation of coal seams than has hitherto been practicable. The important fossils from each horizon are figured so that their recognition in newly exploited areas should not be difficult.

The official descriptions of the geology of the Scottish Highlands north of Inverness are completed with the publication of the memoir on central Sutherland[7]. An area of nearly nine hundred square miles, mapped on Sheets 108 and 109 of the geological map of Scotland, is covered. The region includes the peaks of Ben More Assynt, Ben Loyal, the Griams, Morven and Scaraben and is very thinly populated, being mainly devoted to deer forest and shootings. Geologically, however, it is of great interest since all the great formations of the Northern Highlands fall within its limits. The opening chapters describe the scenery and physical features and summarise the geology. Short chapters dealing with the Lewisian, Torridonian and Cambrian on the west and with the Old Red Sandstone and Jurassic on the east link up the memoir to those already issued. The main features, however, are the descriptions of the vast spread of Moine rocks, of the gneisses of Lewisian type that occur as apparently integral parts of the Moine Series, and of the great masses of granite that have veined and permeated the Moine, producing great injection-complexes that are of outstanding petrographic significance.

A series of memoirs is to be published under the general title: "*Economic Geology of the Fife Coalfields*". The first of these[8] to appear deals with the western part of the county, around Dunfermline, and includes the important coal-mining districts of Valleyfield, Blairhall, Tounhill, Saline and Blairenbathie. The introductory chapter provides a summary of the geology and a brief account of the physical features and of the Old Red Sandstone rocks of the district. This is followed by detailed descriptions of the Calciferous Sandstone and Carboniferous Limestone Series, and special attention is given to the important coalfields of Limestone Coal Group age. The structure is very complicated, as there are many faults, intrusions of igneous rocks, and locally, considerable thicknesses of volcanic ash. To aid in the elucidation of the relations, more than 1,600 boring records have been collected and annotated. Later chapters deal with the superficial deposits and with such economic materials as building stone, road metal and fireclay. The memoir includes a map and a glossary of mining terms.

The memoir devoted to chemical analyses[9] is the outcome of a generally expressed desire that the great number of chemical analyses of British rocks and minerals made by the Geological Survey should be collected and classified, and published in a separate volume. Analyses of igneous and metamorphic rocks and isolated minerals to the number of 611 have been dealt with. They have been brought together from Survey memoirs and other official publications, and additional analyses, hitherto unpublished, have been drawn from the records of the Laboratory. So far as practicable, they have been tabulated under rock-groups; each rock being named and its microscopical characters briefly described. Full details of localities are given, and reference is made in each case to the Survey map and the memoir dealing with the district concerned. The methods usually employed in the chemical analysis of rocks are indicated.

University and Educational Intelligence

EDINBURGH.—On March 2 Sir Ian Hamilton was installed as the Lord Rector, received the honorary degree of LL.D. and delivered his rectorial address, the last part of which was a plea for the control of civil air-craft. "Insist on the Disarmament Commission bringing some concrete act, in regard to the air service, home with them. If we refuse to grapple with this air problem, now in its infancy, within two or three years it will have got quite beyond human control, and then, where's all the use of your learning."

LEEDS.—Mr. A. V. Williamson, head of the Department of Geography in the University, has been elected to the newly-established readership in geography.

LONDON.—The title of reader in experimental physiology in the University of London has been conferred on Mr. H. P. Gilding, in respect of the post held by him at University College.

The following degrees have recently been conferred: D.Sc. degree in anatomy on Mr. Francis Davies, reader at King's College, for three publications on anatomy; D.Sc. degree in physiology on Mr. E. W. Fish, recognised teacher at St. Mary's Hospital Medical School, for a published work entitled "An Experimental Investigation of Enamel Dentine and the Dental Pulp" (Bale, Sons and Danielsson, Ltd., 1933); D.Sc. (Economics) degree on Hans Raj Soni (London School of Economics) for a thesis entitled "Indian Industry and its Problems" (vol. I—"Factors in Industrial Development") (Longmans, 1932).

ST. ANDREWS.—At a meeting of the University Court on March 3 it was intimated that Mr. Frank O. Salisbury has offered to paint and present to the University, a replica of his portrait of Dr. Edward Harkness, founder of the Commonwealth scholarships and the Pilgrim Trust and the benefactor of the University of St. Andrews and many other educational institutions. In addition to the original portrait (which remains in the possession of Dr. Harkness) a replica was painted by Mr. Salisbury for Harvard University. The portrait represents Dr. Harkness in the robe of the LL.D. of St. Andrews. The Court agreed to accept Mr. Salisbury's generous offer.

WALES.—The Council of University College, Cardiff, has received under the will of the late Prof. C. M. Thompson a capital sum of £5,000, the income from which is to be expended on books and periodicals relating to chemistry or certain allied branches of science.

WITH reference to the announcement made in NATURE of February 18, p. 248, of the Lady Tata Memorial scholarships for research in blood diseases, we are informed that the total number of scholarships has been increased to four, and that they are open to candidates from all nations, including India. Nominations in respect of Great Britain and the Dominions will be made by the advisory committee in London to the trustees in Bombay. Applications may be addressed to Dr. H. S. Patel, c/o Messrs. Tata Ltd., Capel House, 62 New Broad Street, London, E.C.2, to Prof. A. Vacha, Calvinstrasse 27, Berlin, N.W.40, or to the Lady Tata Memorial Trustees, c/o Messrs. Tata Sons Ltd., Bombay House, Bruce Street, Fort, Bombay.

Calendar of Nature Topics

The Débacle

March 15.—During the winter, the rivers of Canada, Russia and Siberia are firmly frozen, and the break-up of the ice in spring is an imposing phenomenon, which is termed the 'Débacle'. In southern Canada and southern Russia it begins about the middle of March, but is progressively later in higher latitudes, not coming until May or even, in the extreme north of Siberia, not until June. It lasts from a fortnight to six weeks, during which time the drifting ice masses often form jams, blocking the rivers and causing floods. In the northward flowing rivers of Siberia, in which the upper courses melt first and pour their waters over the still frozen lower reaches, this process is accentuated, and the whole country becomes impassable; Irkutsk, for example, is isolated for a month in May.

Manuring of Grass-Land

In the "Farmer's Kalendar" written by Arthur Young in 1771, we find the top-dressing of grass land set down as a suitable operation for February. The manures that he recommends for this purpose are distinctly nitrogenous and he says, "some of them, particularly soot and malt dust, will show themselves the first heavy showers, in a finer green than the rest of the field; but your proof of it does not arise from fine greens but weight of hay".

More than a century and a half afterwards, the use of quick-acting nitrogenous artificials is now gradually coming into grass-land management as a means of obtaining this vigour which the older writers had observed. Careful work on the effect of early nitrogen on pasture has shown that more rapid growth of grass takes place in spring and the herbage is of particularly high feeding value if grazed while it is still young. In regard to nitrogenous manures, we are more favourably placed than farmers in the last years of the eighteenth century.

We now have available unlimited supplies of active nitrogen compounds at unusually cheap prices, and modern practice exploits their crop-producing power to the full. Owing to the greater activity of present-day nitrates and ammonium salts, as compared with the organic sources of nitrogen on which Arthur Young and his contemporaries had to rely, the time of application to grass-land is now somewhat later than formerly and much of the nitrogen used for the 'early bite' goes on the land in March.

Return of the Gannets

Generally about the end of February or the beginning of March, the gannets (*Sula bassana*) make an appearance at the Bass Rock in the Firth of Forth, from which Linnæus named them, after their short winter absence on the high seas. Exceptionally early returns have taken place in the second week of January. Early in April the first eggs will be laid, and very soon thereafter the whole breeding colony of more than eight thousand individuals will be in full activity. A census made in 1929 revealed the presence of 4,047 nests, and adding to the nesting pairs the numbers of birds which were nestless on account of the destruction of their eggs by herring gulls, the adult breeding gannets of that year numbered 8,294 individuals. In addition, there was an unestimated group of immature and other non-breeding birds which spent most of their time at sea. The shore leave or breeding season of gannets is a generous allowance, for they remain at the Bass from March until the young are able to fly, the general departure taking place in October; but often a rearguard remains to convoy the last fledged of the young, so that in 1929, four hundred birds still hung about the Rock in early November and the last group of about fifty left only on November 13.

Migration of Caribou in Canada

In recent years the caribou or woodland reindeer of Canada have increased in numbers, at any rate in the western part of their range, and with increasing numbers they have reappeared on their old migration routes. Great herds had been observed by Mr. W. H. B. Hoare, during his survey of the Thelon Game Sanctuary in 1928–29, to congregate during the winter in the neighbourhood of Great Slave Lake and Artillery Lake. Early in March a distinct migration northwards began. The moving herds assumed a wedge-shaped formation, the thin edge leading, and during the six weeks which they occupied in passing a particular place, the wedge expanded from a few hundred yards in width to an army which extended from Artillery Lake to Thelon River.

The order of precedence was definite: the wedge tip consisted of a narrow column of old bulls, and during the first two weeks nothing but bulls appeared in the widening phalanx. Then followed two weeks when bulls and cows were about equal in numbers, and the final two weeks saw cows and yearlings make up practically all the remainder of the herd. The migration was a slow movement in extended order, for the animals fed as they marched. During these winter movements the cows travel farther than the bulls, penetrating, towards the south, the fringe of the timber lands, and towards the north passing on to the safe areas selected for fawning. So that the bulls may be said to confine their wanderings to the central part of the caribou range, whereas the cows, starting in the rear of the migration, soon overtake the bulls and pass on through their ranks to the farther north.

Low Temperatures cause Mortality amongst Marine Fishes

The exceptionally protracted spell of cold weather in the early part of March 1929, which was responsible for the mortality amongst shallow-water molluscs already referred to in this Calendar (Jan. 28), also affected the inhabitants of deeper water. The heat stored by the ocean during the summer months is dissipated slowly, so that the northern sea reaches its lowest temperature in March, and in its shallower reaches in the North Sea is, therefore, particularly susceptible to unusually low air temperatures. Such an area lies off the Dutch coast, where the influence of chilled water from Continental rivers is also felt. As a consequence, the catches of bottom fish made during March and April 1929 showed an exceptionally large proportion of dead individuals. Soles seemed to have suffered most, but brill, dabs, plaice, cod and even crabs were brought up dead, and the chafed condition of the surface of their bodies showed that the mortality was not due to the operation of the trawl. Although the earlier reports came from the area off the coast of Holland, similar conditions were found to exist in limited areas to the east and west of the main region, so that in all an area about 200 miles long and 50 miles broad was affected to some extent.

J. R. Lumley and G. T. Atkinson showed that the hydrographical conditions were exceptional, for although the temperature of the North Sea along the shores of Scotland and northern England did not vary much from that normal for the season, the temperature of the Continental shores fell below 0° C. and considerable quantities of ice were present on the coasts of North Germany and Denmark (*Jour. du Conseil*, vol. 4, Dec. 1929). Other happenings, apparently due to the same cold spell, were the increase in the numbers of flounders caught and the presence of numbers of small sturgeon in the southern North Sea, as if they had been forced to migrate from the rivers to the sea by the intense cold.

Societies and Academies

LONDON

Royal Society, March 2. T. M. LOWRY and H. HUDSON: Optical rotatory power. (4) Rotatory dispersion of bornyl and menthyl xanthates, especially in the region of absorption. The fundamental problems of the form of the absorption bands in organic compounds, and of the relationship between absorption, circular dichroism and rotatory dispersion in optically-active compounds, are discussed on the basis of experiments made with the bornyl and menthyl xanthates and dithiourethanes prepared and studied by Tschugaeff. The experimental curves are symmetrical on a scale of wave-lengths. The ratio of the dichroism to the absorption of unpolarised light is approximately proportional to the frequency throughout the greater part of the first band, but on the side of shorter wave-lengths the circular dichroism decreases rapidly, becoming opposite in sign for three of the compounds. It is therefore suggested that the neighbouring absorption band at shorter wave-lengths is also optically active, but that its circular dichroism is opposite in sign to that of the first band. The rotatory dispersion of these compounds has also been measured in the visible and ultra-violet spectrum, including the region covered by the first absorption band. W. F. K. WYNNE-JONES: Acid strength and its dependence upon the nature of the solvent. The dissociation constants of acids in any particular solvent cannot be regarded as a measure of their real relative strengths, since it has been found by Goldschmidt and others that the order of the dissociation constants for a series of acids is dependent upon the solvent. The change in the dissociation constant of an acid on going from one solvent to another is determined partly by the relative basicities of the solvents and partly by the electrical forces between the ions. Since the effect of the former must be the same for all acids, it is proposed to eliminate it by considering not the actual dissociation constants but the constants relative to some standard size. The variations in these relative dissociation constants should then be determined by the electrical forces, and, on the basis of the Born equation, a relationship is deduced.

Physical Society, Jan. 20. SIR ARTHUR EDDINGTON: Notes on the method of least squares. In inferring the value of a physical quantity x from observations, some risk must be accepted. It is therefore presumed that the investigator has made up his mind how much risk he will take, and desires the closest possible limits—the narrowest range of values of x—that he can adopt without exceeding this risk. The aim is to furnish a concise treatment of combination of observations on this basis. Stress is laid on the fact that the method of least squares is justified without the assumption of a Gaussian error law of the observations. Most of the paper deals with quite elementary points, but it ends with a discussion of the more difficult questions which arise in inferring the mean square error of observation from the residuals. MARY BELL and S. E. GREEN: Radiometer action and the pressure of radiation. While the manner in which radiometer action diminishes as the vacuum improves was being investigated, the series of radiometer effects, recorded in the first part of this paper, was observed. Radiation was directed upon light vanes suspended by means of a fine quartz fibre in a flask for a series of vacuum conditions. In the case of a platinised glass vane, at a pressure of a few millimetres of mercury, the deflections on both the glass and the platinised sides were of the order of those registered at the highest vacua obtained. At pressures of about 10^{-2} mm. gas effects developed which were very large in the case of the glass and mica vanes but much less marked with the aluminium vane. With all the vanes, gas action had practically vanished at a pressure of 10^{-6} mm. of mercury. Measurements of radiation pressure were made by the direct method with metal vanes and a vacuum so high that radiometer action was eliminated. The maximum deflections of the suspensions were observed, and the corresponding energy-densities of the radiation were measured by a Callendar cup radio-balance. The results show that the difference between pressure and energy-density varies from + 4 to − 3 per cent. F. J. W. WHIPPLE: The wet-and-dry bulb hygrometer: the relation to theory of the experimental researches of Awbery and Griffiths. Simultaneous values have been published by Awbery and Griffiths of the dew point, of the vapour-content as determined by a gravimetric method, and of the reading of a wet-bulb thermometer, the observations covering a range of air-temperatures from 30° to 100° C. These observations have been rediscussed and it is demonstrated that August's formula by which vapour pressure is deduced from dry and wet bulb readings is valid over the experimental range of temperature. G. I. FINCH and R. W. SUTTON: The control of ignition-coil discharge characteristics. The theory of the ignition coil is developed and is verified by means of the cathode ray oscillograph. It is shown that the spark-gap voltage is constant throughout the life of the inductance component, and that the inductance-component current is oscillatory, but unidirectional. The theory leads to the conclusion, confirmed experimentally, that the closing of the primary circuit during the life of the inductance component rapidly extinguishes the secondary discharge. A contact-breaker, enabling the duration of opening of the primary circuit to be controlled with accuracy over a range between 0 and 2 m. sec., is described. P. VIGOUREUX and S. WATTS: The temperature coefficient of the Weston standard cell. The E.M.F. reached a maximum at about 3°, and at − 20° it was just over a millivolt less than the maximum. The cells behaved satisfactorily at − 16°, but at − 18° freezing took place gradually and was accompanied by a rapid decrease in E.M.F. Frozen cells resumed their normal behaviour when kept at room temperature for about a day. Cooling increased the internal resistance of the cells. An E.M.F. temperature formula valid between − 20° and + 40° is derived.

LEEDS

Philosophical and Literary Society, Dec. 6. E. C. POLLARD : The entry of the disintegrating alpha particle into the nitrogen nucleus and a general relation between heights of nuclear barriers and atomic number. Experiments on nitrogen are described which fix the height of the potential barrier at $4 \cdot 3 \times 10^6$ electron volts. There is an indication of a virtual alpha particle level at 2·2 cm. alpha particle range. The general evidence indicates that the heights of the potential barriers of the light nuclei are proportional to the atomic number. H. M. DAWSON : Ionisation of sulphuric acid. The second stage ionisation of the acid has been determined from reaction velocity data for the hydrolysis of ethyl acetate by the joint catalytic action of the hydrogen and bisulphate ions. The method is probably much more accurate than methods which are based on osmotic (freezing-point, partition) or electrical (conductivity, potential, transport) measurements. The results show that the first-stage ionisation is practically complete and that the second stage ionisation increases from 8·5 to 85 per cent when the concentration of the acid decreases from 0·1 to 0·001 mol. per litre. J. H. PRIESTLEY, LORNA I. SCOTT, and MARJORIE E. MALINS : A new method of studying cambial activity. Details are given of a new 'strip' method of studying the tissues derived from the cambium which seems to be applicable to a wide range of problems connected with radial growth. By the use of this method during 1932, the view that cambial activity recommences in the opening buds and thence spreads basipetally over the old wood of branches and trunk, has been confirmed in the case of some thirty species of hardwoods and six species of softwoods. (See NATURE, 130, 494, Oct. 1, 1932.) GEORGE COCKERHAM : Variations in the total nitrogen content of normal and leaf-roll potatoes. A preliminary study of diurnal variations in the total nitrogen content of the leaves (laminæ and petioles) of normal and leaf-roll potato plants with a note on the distribution of total nitrogen in normal and virus infected tubers.

PARIS

Academy of Sciences, Jan. 23 (*C.R.* 196, 225–304). CHARLES NICOLLE, J. LAIGRET and P. GIROUD : The passage of the virus of exanthematic fevers by the digestive canal in the rat. Experiments were made with three types of virus : the virus was found to be capable of traversing the wall of the alimentary canal of rats. FRANCESCO SEVERI : Some new theorems in algebraic geometry. V. LALAN : The affine signification of the pseudo-arc and of the pseudo-curvature of minimal curves. C. POPOVICI : The necessity of introducing a new idea concerning the discontinuity. GEORGES GIRAUD : Correction to a recent communication. ARNAUD DENJOY : The calculation of the coefficients of trigonometrical series. KING-LAI HIONG : Meromorph functions of infinite order. L. ESCANDE and P. DUPIN : The similitude of transitory regimes in movements of rotation. JACQUES VALENSI : Stream lines in the flow round a cylinder of revolution with a high Reynolds number. ROBERT GIBRAT : The existence of a dangerous rotation velocity, independent of the balancing, for certain turbo-alternator groups. JACQUES WINTER : The phenomena of resonance in undulatory mechanics. COMAS SOLA : The radial velocity of some nebulæ. F. LINK : The photometric theory of eclipses of the moon. D. BARBIER : Remarks on the dynamic parallaxes of double stars. A reply to some criticisms of Finsen. H. BORDIER : The production of Merget's phenomenon by d'arsonvalisation with short waves. Merget's phenomenon, the adsorption of gas when moisture is expelled by heat, has been studied for liquids other than water : data are given for methyl alcohol, acetone and ethyl ether. P. BIQUARD : An optical method for the measurement of the absorption of ultra-sound waves by liquids. If I, I_0, are the light intensities transmitted by the cell when the ultra-sound waves are present and absent respectively, the ratio of these intensities varies linearly with the energy of the ultra-sound waves. YEU-KI-HENG : The action of aluminium salts on alkaline tartrates. CH. BEDEL : The magnetic susceptibility of ferrosilicons rich in silicon. Figures are given for twelve alloys with silicon content varying from 34·64 to 99·86 per cent. All these alloys were paramagnetic. At the composition corresponding to the compound $FeSi_2$ there was a large increase in the magnetic susceptibility. SERVIGNE : The existence of a polonium acetylacetonate. This substance was found to be soluble in warm chloroform, benzene, alcohol and acetone. In chloroform solution the substance was not sensibly ionised. From the study of the isomorphism of known acetylacetonates, the radioelement would appear to be tetravalent. MLLE. SUZANNE VEIL : The periodic precipitation of mercuric iodide. A. PERRET and R. PERROT : Contribution to the study of the cyanide-cyanamide equilibrium. Sodium cyanide was heated with chlorides of lithium, calcium, barium, strontium, magnesium, beryllium, zinc and cadmium, in presence of iron powder as catalyst, and the proportion of cyanamide determined. FRANCIS MEUNIER : The corrosion of welds of mild steel. CHARLES BARON : Carburation in internal combustion motors. P. CARRÉ and D. LIBERMANN. The reaction of thionyl chloride upon phenol. M. BACKÈS : The action of phosphorus oxychloride upon some aldehydes. J. A. MULLER and MLLE. EGLANTINE PEYTRAL : The sudden pyrogenation of ketene. Analysis of the gases obtained by rapidly passing ketene through a platinum tube at 1150° C. The hypothesis that the primary decomposition is into CO and CH_2 is consistent with the results. S. GOLDSZTAUB : The crystalline structure of sodium ferrite. L. ROYER : The orientation of crystals of organic substances depositing in contact with a mineral with ionic structure. G. FRIEDEL : Remarks on the preceding paper. MLLE. HENRIETTE ALIMEN : Important erosion of the Stampian in the Paris basin. MARCEL BADOUIN : An intentional fabrication of an engraving of a horse's hoof on granite, by means of a stone tool. Prehistoric engravings of animal's hoofs on granite rocks have been found in France and elsewhere : the author proves experimentally that such engravings can be readily made on granite with flint tools. EMILE F. TERROINE and MLLE. SIMONE VALLA : The comparative value of various protein foods in growth. The use of a protein food for young animals should not be based on the total nitrogen present, but on the proportion of the protein which can be utilised by the organism for the production of new tissue. Barley is markedly superior to wheat in this respect. P. MEZINCESCO : The utilisation of amino nitrogen by the animal organism. L. BUGNARD, P. GLEY and A. LANGEVIN : The recording and measurement of the blood pressure. The method described, based on the effect of the pressure changes on a piezoelectric quartz crystal, gives a record of the changes in arterial pressure and also the absolute pressure. **Albert Lambrechts**: The spectrographic study of phlorhizine and its derivatives. The ultra-violet absorption spectrum of phlorhizine. **Maurice Piettre**: The flocculation in the organism of colouring matters, chemically defined artificial colloids. **Mlle. H. F. M. Petter**: The structure of *Sarcina gigantea*. **E. Manoussakis**: A method of immunising the rabbit against dysenteric infection.

Forthcoming Events

Monday, March 13

Royal Geographical Society, at 5.—Capt. C. R. P. Diver: "The Physiography of South Haven Peninsula, Studland Heath, Dorset".

Institute of Industrial Administration, at 6.30—(in the Lecture Hall, Institute of Hygiene, 28, Portland Place, W.1).—A. P. M. Fleming: "Research in Relation to Industry".

Tuesday, March 14

Royal Institution, at 5.15.—Sir James Jeans: "Modern Astronomy" (succeeding lectures on March 21, 28 and April 4).

Wednesday, March 15

Royal Meteorological Society, at 7.30—(G. J. Symons Memorial Lecture).—P. M. S. Blackett: "Cosmic Radiation".

Royal Society of Arts, at 8.—Prof. W. A. Bone: "The Chemistry of Hydrocarbon Combustion".

Thursday, March 16

Chemical Society, at 8.—Discussion on "The Chemical Constitution of Oestrin" to be opened by Dr. G. F. Marrian.

Friday, March 17

Physical Society, at 5—(at the Imperial College of Science and Technology).—Annual General Meeting.

Royal Institution, at 9.—Prof. W. L. Bragg: "The Structure of Alloys".

Saturday, March 18

Royal Anthropological Institute, at 2.15—(at St. John's College, Cambridge).—Dr. L. S. B. Leakey: "Discoveries of Human Remains at Kanam and Kanjera (Kenya)".

Official Publications Received

GREAT BRITAIN AND IRELAND

The Journal of the Institution of Electrical Engineers. Edited by P. F. Rowell. Vol. 72, No. 434, February. Pp. 93–188+xiv. (London: E. and F. N. Spon, Ltd.) 10*s*. 6*d*.

The British Wood Preserving Association. Circular No. 1: The Preservative Treatment of Estate and Farm Timber. By R. C. B. Gardner. Pp. 36+2 plates. (London.) 6*d*.

Department of Scientific and Industrial Research. Report of the Fuel Research Board for the Year ended March 31, 1932; with Report of the Director of Fuel Research. Pp. viii+96. (London: H.M. Stationery Office.) 2*s*. net.

Royal Society of Arts. Tenth Annual Competition of Industrial Designs, 1933. Pp. 32. (London.) 4*d*.

Department of Scientific and Industrial Research. Building Science Abstracts, Vol. 5 (New Series), No. 12, December. Abstracts Nos. 2169–2427. Pp. 399–529. (London: H.M. Stationery Office.) 1*s*. net.

Air Ministry: Aeronautical Research Committee: Reports and Memoranda. No. 1476 (T. 3208): Stressless Corrosion followed by Fatigue Test to Destruction on Aluminium Crystal. By Dr. H. J. Gough and G. Forrest. Pp. 11+8 plates. 1*s*. net. No. 1483 (T. 3223): Periodic Flow behind an Airscrew. By C. N. H. Lock and D. M. Yeatman. Pp. 15+6 plates. 1*s*. net. No. 1493 (T. 3262, 3294, S. 121): Stability on the Water of a Seaplane in the Planing Condition. By W. G. A. Perring and H. Glauert. Pp. 60+4 plates. 3*s*. net. No. 1494 (T. 3291): Airflow about Aeroplanes shown by Wool-tufts. By B. Melvill Jones and J. A. G. Haslam. Pp. 12+12 plates. 1*s*. 3*d*. net. (London: H.M. Stationery Office.)

Forestry Commission. Bulletin No. 14: Forestry Practice; a Summary of Methods of establishing Forest Nurseries and Plantations with Advice on other Forestry Questions for Owners and Agents. Pp. 108. (London: H.M. Stationery Office.) 2*s*. net.

OTHER COUNTRIES

Canada: Department of Mines: Geological Survey. Economic Geology Series, No. 11: Rare-element Minerals of Canada. By H. V. Ellsworth. (No. 2314.) Pp. v+272. 40 cents. Economic Geology Series, No. 12: Manganese Deposits of Canada. By G. Hanson. (No. 2317.) Pp. v+120. 20 cents. (Ottawa: F. A. Acland.)

Canada: Department of Mines; National Museum of Canada. Bulletin No. 69 (Biological Series No. 18): Methods of Collecting and Preserving Vertebrate Animals. By R. M. Anderson. Pp. v+141. 25 cents. Bulletin No. 70: Annual Report for 1931. Pp. 119. (Ottawa: F. A. Acland.)

University of California Publications in Zoology. Vol. 38, No. 13: Postjuvenal Molt and the Appearance of Sexual Characters of Plumage in *Phainopepla nitens*. By Alden H. Miller. Pp. 425–446+plates 8–9. (Berkeley, Calif.: University of California Press; London: Cambridge University Press.) 25 cents.

R. Osservatorio Astrofisico di Catania. Annuario 1933. Pp. iv+39. L'Attività del Sole nell'anno 1932. Pp. 14. (Catania.)

Merentutkimuslaitoksen Julkaisu Havsforskningsinstitutets Skrift. No. 80: Vedenorkeusarvoja 1929 ja 1930. By S. E. Stenij. Pp. 84. 35 Fmk. No. 81: Croisière thalassologique et observations en bateaux routiers en 1931. Rédigé par Gunnar Granquist. Pp. 38. 20 Fmk. No. 82: Regelmässige Beobachtungen von Temperatur und Salzgehalt des Meeres Juli 1930—Juni 1931. Herausgegeben von Gunnar Granquist. Pp. 44. 25 Fmk. No. 83: Strom- und Windbeobachtungen an den Feuerschiffen in dem Jahren 1930 und 1931. By E. Palmén. Pp. 85. 35 Fmk. No. 84: Havsforskningsinstitutets värksamhet år 1931. By Rolf Witting. Pp. 15. 10 Fmk. No. 85: Översikt av isarna vintern 1931–32. By Gunnar Granquist. Pp. 50. 35 Fmk. No 86: Untersuchungen über gelöste Phosphate und Stickstoffverbindungen in den nordbaltischen Meeresgebieten. By Kurt Buch. Pp. 30. 20 Fmk. (Helsinki.)

Societas Scientiarum Fennica: Commentationes Physico-Mathematicae. VI, 14: Über die Einwirkung des Windes auf die Neigung der Meeresoberfläche. By E. Palmén. Pp. 50. 15 Fmk. VI, 16: Zur Theorie der Wasserschwingungen in einem begrenzten Meeresbecken, mit besonderer Berücksichtigung des Einflusses von Luftdruck. By S. E. Stenij. Pp. 80. 30 Fmk. VI, 26: Ein selbstschreibender Apparat für Ausmessung von Mareographenkurven. By S. E. Stenij. Pp. 8. 4 Fmk. (Helsingfors: Akademische Buchhandlung.)

Proceedings of the Imperial Academy. Vol. 8, No. 10, December. Pp. xxix–xxxi+475–520. (Tokyo.)

Memoirs of the Indian Meteorological Department. Vol. 25, Part 9: On Evaporation and its Measurement. By Dr. S. K. Banerji and H. M. Wadia. Pp. iii+291–325+3 plates. (Calcutta: Government of India Central Publication Branch.) 2 rupees; 3*s*. 6*d*.

India: Meteorological Department. Scientific Notes, Vol. 5, No. 51: A Preliminary Study of Rainfall at Quetta. By A. K. Roy and R. C. Bhattacharya. Pp. 49–61. (Calcutta: Government of India Central Publication Branch.) 10 annas; 1*s*.

Holiday Courses in Europe, 1933. Compiled by the League of Nations' Institute of Intellectual Co-operation. Pp. 60. (Paris: Institute of Intellectual Co-operation; London: George Allen and Unwin, Ltd.) 2*s*.

Royal Observatory, Hong Kong. Weather Observations from Ships (Appendix to Hong Kong Observations, 1931). By C. W. Jeffries. Pp. 41. (Hong Kong.)

Department of Agriculture: Straits Settlements and Federated Malay States. General Series, No. 11: Reports of Agricultural Field Officers for the Year 1931. Pp. iv+143. (Kuala Lumpur.) 50 cents.

Collection des travaux chimiques de Tchécoslovaquie. Rédigée et publiée par E. Votoček et J. Heyrovský. Année 5, No. 1, Janvier. Pp. 48. (Prague: Regia Societas Scientiarum Bohemica.)

Państwowa Rada Ochrony Przyrody. Nr. 34: Sprawozdanie z Dzialalności Państwowej Rady Ochrony Przyrody w Roku 1932. By Prof. Dr. Wladyslaw Szafer. Pp. 15. Ochrona Przyrody: Organ Państwowej Rady Ochrony Przyrody. Rocznik 12. Pp. iv+190+4 plates. (Krakow: Państwowa Rada Ochrony Przyrody.)

Mellon Institute of Industrial Research. Bibliographic Series, Bulletin No. 3: A Select, Annotated Bibliography on the Hygienic Aspects of Aluminium and Aluminium Utensils. With a Preface by Edward R. Weidlein and an Introduction to George D. Beal. Pp. xi+80. (Pittsburgh, Pa.)

The Science Reports of the Tôhoku Imperial University, Sendai, Japan. First Series (Mathematics, Physics, Chemistry), Vol. 21, No. 5, December. Pp. 727–935. (Tokyo and Sendai: Maruzen Co., Ltd.)

Nyasaland Protectorate: Geological Survey. Bulletin No. 4: The Portland Cement Clays of Lake Malombe; an Account of Investigations carried out jointly by the Geological Survey and the Imperial Institute during the period 1928 to 1931. By Dr. F. Dixey. Pp. 11. (Zomba: Government Printer.)

The Journal of the Botanical Society of South Africa. Edited by R. H. Compton. Part 18, 1932. Pp. 32+4 plates. (Kirstenbosch, Newlands.)

Argeologiese Navorsing van die Nasionale Museum, Bloemfontein. Deel 1, Stuk 5–7: Studies in Native Animal Husbandry, 8: Native Milking Pails, by H. H. Curzon, A. D. Thomas and W. O. Neitz; 'N Nuwe Suid-Afrikaanse Kultuur, by Dr. Ir. E. C. N. Van Hoepen; Die Oog van die Leeu, by Dr. Ir. E. C. N. Van Hoepen. Pp. 55–64+plates 20–24. (Bloemfontein.)

Ministry of Agriculture, Egypt: Technical and Scientific Section. Bulletin No. 119: Investigations on the Wilt Disease of Egyptian Cotton caused by various Species of Fusarium. By Dr. A. Fikry. Pp. iv+106+16 plates. (Cairo: Government Press.) 10 P.T.

Columbia University Bulletin of Information. Thirty-third Series, No. 16: Announcement of Professional Courses in Optometry for the Winter and Spring Sessions, 1933–1934. Pp. 31+3 plates. (New York City.)

Science and Service in Universities Overseas

IT cannot be gainsaid that the inhabitants of England, and of London in particular, are prone to assume an air of superiority over visiting representatives of the Dominions, even when the latter are themselves engaged in the task of building up new universities at the outposts of the British Empire. Necessarily the Empire must have a centre, which can only be London, but acceptance of this postulate does not preclude first-class work on a particular subject being carried out at a university thousands of miles away. It is only required to mention the names of Rutherford and Soddy in connexion with McGill University to establish this point. Whilst it is desirable and indeed excellent to have a cultural centre for the Empire, it would be disastrous if the advantages of proximity to it had the effect of making the foremost teachers, old and young, reluctant to work at the circumference, where there is much educational work of the highest importance to be done.

Among those who take the view—and there can be few who oppose it—that never was the closest union with the Dominions as a whole more essential to the Mother Country and that indeed her future prosperity largely depends on strengthening the bonds which unite the Empire, there is a keen desire to see the best possible use made of the intellectual ability of the Empire to this end. Apart from those few philosophers who can only work under conditions which are to-day's equivalent of monastic seclusion, it would do all the good in the world to most of the younger scientific workers to spend a year or more out in the Empire making contact with life as it is lived under somewhat different conditions from those which prevail at home, conditions which are claimed by some to be nearer the actualities of life.

The basic ideas we desire to develop are, first, the need for the universities of the Dominions to be able to draw on the best brains in the Empire for their professoriate. The material to be taught there is worthy of the teacher; the problems, both pure and applied, to use the hackneyed terms, are there in plenty. Secondly, those who accept such posts should be placed at no disadvantage in their future professional career. As this is at the moment perhaps the crux of the matter, it may be considered in more detail. At the end of the nineteenth century and for a decade in the twentieth it was usual for the enterprising sons of large families to cross the seas to find work under conditions of greater freedom than at home: for all classes the opportunities were greater than at home, and the rising man of science gained a professorship at a substantial salary years before he could have achieved this in Britain. To-day things have changed: the working man no longer emigrates, for a variety of reasons which do not concern us here; the young scientific worker finds sufficient opportunities, including some measure of financial security, to keep him at home and he is unwilling to sacrifice the advantages of scientific centralisation. It must be admitted that part of his reluctance to face life under new conditions in the Dominions is due to his womenfolk, who, however enterprising they may be in sensational sports stunts, are on the whole unwilling to face the different and possibly harder life in the Dominions. It is true the burden of this falls mainly on their shoulders, whereas the daily round of the husband in his laboratory is much the same as at home. The difficulties should be realised in the Dominions, and a specially warm welcome extended to the 'Frau Professor' until she is thoroughly acclimatised to the new conditions.

Although, as Prof. Stanton Hicks emphasises in a letter we are publishing elsewhere in this issue (p. 397), the inducements to attract and retain good men in the Dominions have to be greater than in the past, there is one factor working in the opposite direction which should help, namely, the ever-quickening of transport, which makes it possible to retain much closer contact with England. Eastern Canada is within a week of home, at least in the summer, and both South Africa and Australia are less remote than at one time, and even the cost of the passage is less onerous. Adding the fact that people in the Dominions are used to long journeys, it becomes possible, other things being equal, to visit the homeland much more often than has been customary in the past. Amongst other things we contemplate the payment of a passage to England and back every few years under the conditions of the professorship; this is usual in the case of commercial employees who are sent to the East by their employers. The principle of the sabbatical year is now quite established in the United States, and it should be possible to adopt it, with improvements, within the British Empire. Here the Royal Society might help. It could each year send out one or more of its research professors to the Dominions to take the place of the local professor, who would come home to do a year's research in a British laboratory. We feel convinced that the effects of such exchange on both parties would be remarkable and would in a few years have a profound influence on the whole university movement in the Dominions.

There should be an unwritten law not to overlook workers in the Dominions when awarding scientific honours or making elections to vacant chairs. The Royal Society has always awarded its fellowship with liberality to overseas workers, but it is desirable that the feeling should prevail that the axiom 'out of sight, out of mind' does not apply to them. The difficulty of interviewing candidates overseas for a vacant chair might be overcome by the selection of a carefully chosen panel of seniors, who would meet and record their impressions of them before they first crossed the ocean and during every subsequent visit to the Mother Country. Such a panel would be able to make impartial reports when necessary.

We would go even further in encouraging a knowledge of Empire conditions among professors, by definitely giving preference when filling the senior positions at the universities at home to men who have had such experience. In their turn, the universities in the Dominions must accept the idea of a five years' tenure of their professorships. There will, no doubt, be strong objections to this suggestion because of its disturbing effect on the regular routine of the university, but in the long run there can only be benefit from the new ideas brought in by the new man and the new stimulus he will give to staff and students alike. It is in no way suggested that the term of office should be limited to five years, only that it should form a period after which a teacher would be considered to have discharged his obligations should he wish to return to England.

It is an open question, not suitable for debate here, whether some chairs should not be definitely limited to a five years' period; others again, after a period of probation, might well be for the period of active life. In those sciences which are in close connexion with the active industrial development of a Dominion, we believe there is much to be gained by a regular change in the occupant of a chair: we can even visualise the new man coming out of industry, the retiring professor entering or returning to industry, to the advantage of individuals, students, industry and the university. There must be a real contact between the university and the town and State in which it is situated; it must play a part in the agriculture, in the industries, in the development and in the life of the community and be far, far more than a high school to which the citizens send their sons and daughters. 'Town and gown' must not be different and opposing unities; the gown must be thrown round the town and the townspeople made proud to wear it.

We have stressed this, the practical function of a university overseas, without any intention of minimising or detracting from the other functions it should have, that of teaching and that of pure research. The best kind of teaching is so much a matter of inspiration—a few words from the right man can make a dull subject an entrancing mystery—that this is largely a question of the individual teacher. Unfortunately, universities must grant degrees, and degrees involve examinations, which in their turn mean a syllabus and courses of instruction, none of which is really education for life's battles in the true sense of the word. There is no hope of changing this state of affairs at the moment at home, though overseas the authorities may perhaps be more enlightened since they are more closely in touch with the realities of life. So long as there are examinations, teaching in the main must be directed to covering the facts contained in a comprehensive syllabus and not to the presentation of a logical approach to the subject itself. Apparently the good students survive even the examination and its preparation, and the inferior might never learn the subject anyway, so the old bad ways are perpetuated.

There are several aspects of the research question at the overseas universities. A good man will prosecute the research in which he is interested anywhere, whatever the conditions. Sir Daniel Hall has reminded us that research proceeds from an artistic impulse, so that it is not under control. The best results in the past have not come out of the institutions with the finest equipment, witness Sir William Ramsay's laboratory in London and that of Emil Fischer in the Dorotheen Strasse, Berlin, both the scene of epoch-making discoveries. More difficult to overcome is the lack of stimulus resulting from the regular contact with other workers. However, the typewriter makes it possible to write lengthy letters with a minimum of effort, which, with the good postal facilities available, should enable the written to replace verbal intercourse. The work achieved in the laboratories of the British Empire—there is no need to mention names—makes it abundantly clear that the right type of man can produce the best work in them and that he need not fear intellectual starvation. It should perhaps also be said that in many of the Dominion laboratories the equipment is of the best, even in advance of much of what we have at home. It is true that modern physics demands a super equipment, such as has just been installed at Cambridge, but there are many other fields of scientific endeavour where the apparatus and materials necessary for a research can be packed up in a few cases and moved from one laboratory to another. The prolific researches of the professors of chemistry at Oxford, for example, give no indication of having suffered as the result of their having worked in several laboratories in the Old World and the New.

The developments in the United States afford an illustration of how universities in cities in remote States, possessing a very inferior cultural background, have developed here and there under the leadership of individuals of the right type into first-class schools of research and teaching. It is true the distances from Yale or Harvard to these centres are small, but a decade or so back it was very difficult to persuade the best men to take up these positions in the Middle West.

We have still to consider our theme in relation to graduates of the Dominion universities who come, as indeed they should, to the Mother Country for post-graduate work. Should they stop in England or return to take up posts in the countries whence they came? The temptation must vary with the individual. Some will feel family ties and associations and the pull of the freer life and better climate, others will feel the beckoning finger of the academic atmosphere. Each must choose for himself in relation to his inclinations, but one thing is certain, that we at home, spectators in the auditorium, must applaud him who goes abroad as loudly as the man who stays at home. The success of the Empire depends rather on the deeds of the man on the spot than on speeches at Westminster, and no insular narrow-mindedness must be allowed to stand in the way of giving him the best men as his teachers.

It is perhaps trite to say the world is at the cross-roads. There are many who think that for Britain, one way points towards sterling and the Empire and the other towards gold and uncertainty, if not chaos. If we choose the former and build on the foundations laid at Ottawa, unite with people of our own blood and our own tongue into a closer union, leading, let us pray, to Imperial greatness, then it must be remembered that we are all free men of independent habit of mind, so that Imperial unity means Imperial independence, a centrifugal force opposed to centralising everything intellectual in the capital of the Empire.

In the world as it is to-day, no unit is big enough to stand alone. Economic groupings are necessary, the most beneficial being that of a big industrial nation with a big agricultural nation. Just as some forms of agriculture are so uneconomic that their practice results in raising the cost of living, so also the costs of manufacture must be kept low if Britain is to be the great central industrial country. Success in attaining these ends lies in the advances that science can make, such as will enable, for example, the big agricultural business to compete with the one-man farm, the rationalised industry to meet the competition of the small business. As regards the Dominions, it is clear that when a country has great resources of raw material, it will certainly attempt to establish its own industries, but it should only afford them a protection by tariff when they are reasonably assured of sound opportunities for success.

If the industries of the Dominions, agricultural and otherwise, are to prosper, research at the universities must be fostered, for in agriculture there are no great corporations to endow research. Sheltered places must be provided for the research workers and the shelter must be of a nature that will attract the best. Only thus shall be established our claim to Imperial greatness.

Evolution and Philosophy

The Scientific Basis of Evolution. By Prof. T. H. Morgan. Pp. 286. (London: Faber and Faber, Ltd., 1932.) 15*s*. net.

THE present book, based on a course of lectures at Cornell University, represents the views of a leading geneticist concerning the present position as regards evolution. It contains little that is new to the geneticist, and its statements are apparently designed mainly for the more general reader. The earlier chapters are concerned with such topics as the cellular basis of heredity, Mendelian inheritance and the genes, variability, adaptation and natural selection, mutation, sexual selection, and the evolutionary significance of embryonic development. The last four chapters are essentially a critique of (1) the well-worn theme of inheritance of acquired characters; (2) the social evolution of man; (3) the conception of the 'order of Nature', and (4) of metaphysical interpretations of evolution.

Although the work deals mainly with the more recent developments, occasional pages might have been taken from almost any textbook in the last fifteen years. There are a few inaccuracies, especially as regards plant genetics. For example, it is stated that *two* cases are found where interspecific crossing has produced new stable types with a higher chromosome number. The list of such cases in plants now extends to at least eighteen, and the most significant ones from an evolutionary point of view are not mentioned. Similarly, the statement (p. 44), "Whether this growth [of the chromosomes] takes place at the time of splitting, or after the halves have moved apart, is not certainly known at present", can only be regarded as a very inadequate statement concerning present knowledge of the growth and division of chromosomes.

In the chapter on mutations, the frequency of viable mutants in *Drosophila* is estimated at one in five to ten thousand flies. The discussion of the relation between the mutation theory and natural selection reaches the conclusion that some of the mutants will be an improvement, either on the old characters, or in a somewhat different environment and will therefore be incorporated into the species. It requires more than this, however, to show that mutations furnish the material for evolution. It would seem reasonable to expect that evidence on this head could be obtained in part by a comparison of the mutations in any group of organisms with the interspecific differences found in that group. Hitherto very little work of this kind, involving both mutational and taxonomic studies, has been done.

Elsewhere (p. 182) Morgan concludes that there may have been as many genes in the earliest organisms as at present. Such a view, if pressed to its conclusion, can only mean that the genic differentiation of the chromosomes of an amœba is as great as in man, a conclusion which would certainly not be accepted by many biologists. It would seem that the gene theory can only be reasonably maintained on the assumption that the chromosomes of higher organisms are more differentiated along their length than those of the lower forms. The opposite view savours more of Bonnet's *emboîtement* theory than of evolution in a real sense.

On p. 205 the extraordinary statement appears, that "Only a few strictly dominant mutational changes are known in man", brachydactyly being cited as an example. In the literature of the subject, dominant abnormalities are very frequent, and probably even more so than recessives. The latter, however, owing to their nature, may of course be more numerous in the human germ-plasm.

In his first and last chapters especially, Morgan wields a stick against the "metaphysicians and philosophers of sorts". Whitehead, Jeans, Eddington, J. S. Haldane, Smuts and others in turn come in for castigation. The author's attitude may be gathered from the statement (p. 239), "By patience and industry and intelligence, biologists hope to advance their work. But so long as they have not found convincing evidence, it is an 'open season' for philosophers, who are too impatient to wait, but must add the biological field to their speculations." Although "philosophers" are thus warned off the field of biology, yet the author appears to recognise that the philosopher may have his function in the scheme of things when he says that "the scientist cannot afford to be entirely contemptuous of the history of philosophic and metaphysical thought, or to assume an arrogant disregard for it". But he accuses metaphysicians of placing limitations on exploration by scientific methods, and of assuming that the methods of science can have no bearing on the topics "reserved by metaphysicians". Behind the mechanistic position which Morgan defends there appears to be the assumption that when a man ceases to be a mechanist in the generally accepted sense, he *ipso facto* loses his scientific status.

This book will doubtless claim the interest of a wide range of readers. R. RUGGLES GATES.

Destructiveness of Earthquakes

Earthquake Damage and Earthquake Insurance: Studies of a Rational Basis for Earthquake Insurance; also Studies of Engineering Data for Earthquake-Resisting Construction. By J. R. Freeman. Pp. xiii + 904. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1932.) 7 dollars.

DR. FREEMAN, whose death has recently been recorded in our columns, broke new ground in this large volume, for no other work has yet been published that is devoted exclusively to the damage caused by earthquakes, the methods by which it may be lessened, and the covering of loss by insurance. Naturally, he deals for the most part with the earthquakes of the United States, though chapters are also given to recent shocks in Italy, New Zealand and Japan. But, for workers in all countries, the data here collected with the admirable series of illustrations will be found most useful. The chief regret that one feels in closing the volume is that the author lacked the time for its careful revision. The whole book might easily and with great advantage have been condensed to perhaps half its present length.

As Dr. Freeman points out, there is no region in the United States or Canada that can be regarded as wholly immune from the possibilities of earthquake damage, though the risk is far less on the east, than on the west, side of the Rocky Mountains. Two of the greatest earthquakes in the country—the New Madrid earthquake of 1811 and the Charleston earthquake of 1886—occurred, however, in districts that had been almost, though not quite, free from disturbance since the discovery of America. A very important feature of nearly all American earthquakes is that serious damage is confined within a comparatively small area. The Charleston earthquake, for example, though it was felt to a distance of 800 miles from the centre, was destructive to property only within three areas, each containing less than one square mile. Indeed, Dr. Freeman states that the area of severe destruction in American earthquakes has never exceeded 10 square miles, except in the New Madrid earthquake of 1811, the Owens Valley earthquake of 1872 and the Californian earthquake of 1906, and in the last-named was not more than 400 square miles.

Moreover, even within the central area, the ratio of damaged to undamaged houses is usually small. The buildings that are badly injured in an earthquake, whether of American or other origin, have nearly always been of weak and inferior construction. Well-built structures of wood or brick, or of squared stone laid in strong mortar, have usually withstood an earthquake shock. Even in the destructive earthquakes in Japan in 1923, Santa Barbara in 1925, and Nicaragua and New Zealand in 1931, buildings of monolithic reinforced concrete, deposited round well-designed steel skeletons, have as a rule survived unharmed. Earthquake-proof buildings may thus be erected up to 100 ft. in height, within reasonable limits of cost, whatever the ground on which they stand; and Dr. Freeman therefore considers that it would be possible to combine earthquake insurance with fire insurance in the same policy at an increase in cost that would be small for the whole region east of the Rocky Mountains, and in California at an amount far less than that at present charged.

No one can deny that many good buildings have been seriously injured by earthquakes, but in estimating insurance hazards we have to deal with averages. The photographs of ruin that are included in published accounts are designed to thrill the reader. There would be no interest in depicting the buildings that have sustained little or no injury. In Charleston in 1886, for example, the ratio, as Dr. Freeman calls it, of earthquake damage to sound value scarcely exceeded 10 per cent. Out of 6,956 buildings examined, only 102 were ordered to be pulled down. In the remaining houses, the damage consisted for the most part merely of broken chimneys or cracks in walls or plaster. In the published accounts the emphasis was laid on the wreckage; little was said about the buildings, of which the author gives nearly fifty photographs, that passed through the trial unharmed.

The strongest earthquakes in North America within the historical period are those of Quebec in 1663, New Madrid in 1811, Owens Valley in 1872, Charleston in 1886, San Francisco in 1906 and Santa Barbara in 1925. It is improbable that an earthquake more violent than any of these will visit the country. Thus, the author suggests that an area of 2,500 square miles may be considered as the limit of serious destruction, and that within this area an average loss ratio of 5 per cent would be an excessively generous allowance. Taking into account the known frequency of destructive earthquakes in the various regions of the United States, he concludes that (rendered in English money) the following rates per £100 value of the property would cover the probable loss of damage from earthquakes, apart from working expenses and profits: California within fifty or sixty miles from the coast and including the Imperial Valley, 2*s.*—after the Santa Barbara earthquake of 1925, the rates actually charged were 5*s.*–8*s.* per £100, according to the type of building—Californian Mountains east of the Great Valley, 1*s.* 5*d.*; Washington and Oregon within a hundred miles from the coast, 1*s.* 2*d.*; Rocky Mountain-Wasatch region, 7*d.*; Great Lakes and Mississippi region below the Missouri confluence and within ten miles of the bottom lands, 5*d.*; the Atlantic region within fifty miles from the coast, 2½*d.*; and more than fifty miles, 1¼*d.*

Electrolytes

Elektrolyte. Von Prof. Dr. Hans Falkenhagen. Pp. xvi + 346. (Leipzig: S. Hirzel, 1932.) 23 gold marks.

THE author of this volume, now professor at the University of Cologne, studied at Zurich under Debye, and then in the United States at Madison, where he came into close contact with American workers on aqueous solutions. His book on electrolytes is only about one-third of the length of Walden's well-known monograph, but is a much more formidable work, since it includes 759 numbered equations, and demands a standard of mathematical knowledge which may perhaps be common amongst physicists, but is certainly rare amongst chemists.

The historical electrochemistry of Faraday is summarised in a single paragraph, and the whole output of the Ostwald school is condensed into a few pages, in which data which were formerly quoted as evidence in support of Arrhenius's 'classical' theory of electrolytic dissociation are now cited as proof of the inadequacy of that theory. The subjects which the author excludes from his principal text are, however, referred to in footnotes, where abundant references are given to the relevant literature, for example, on acids and bases, homogeneous catalysis, pseudo-electrolytes, etc.

After thus clearing the ground in three short chapters, occupying only 38 pages, the author provides two chapters on activity and on the anomalies of strong electrolytes, followed by five chapters dealing with the explanation of these anomalies by the Milner-Debye theory, as applied to the thermodynamics, conductivity and viscosity of aqueous electrolytes. A chapter on concentrated solutions is of interest as evidence of a reaction from the first hasty impression that all strong electrolytes are completely ionised under all conditions. In this chapter methods are discussed for calculating the true degree of dissociation, not only of formic and iodic acids, but also of salts such as potassium iodide, which crystallise in typical ionic aggregates. A final short chapter deals with the statistical basis of Debye's theory as developed by R. H. Fowler and by Kramers.

The book as a whole can scarcely be regarded as suitable for 'arm-chair' reading, but is perhaps not unduly difficult in view of the character of

post-War work on electrolytes. It will therefore be useful to readers who are anxious to bring their knowledge of the subject up to date; and those who are repelled by the mathematical equations may be attracted by the curves which are used to show the deviations of even the best-behaved electrolytes from the ideal laws laid down for them. An introduction by Prof. Debye sets a seal of authority on this exposition of the Milner-Debye theory of electrostriction.

Short Reviews

Plane Algebraic Curves. By Prof. Harold Hilton. Second edition. Pp. xv + 390. (London: Oxford University Press, 1932.) 28*s.* net.

IN this new edition of Prof. Hilton's able work on the theory of plane algebraic curves, which was first published in 1920, advantage has been taken to recast several important chapters without disturbing the original pagination. Those who are acquainted with the first edition will agree that the author has considerably clarified the text in these chapters and has added fresh proofs to several important theorems, notably on pp. 76, 101 and 199. This should certainly stimulate a greater interest in an admittedly abstract branch of analysis. A considerable portion of the matter is the result of the author's own investigations into the subject. Especially is this the case in the chapters on quadratic transformations, derived curves, unicursal quartics and quartics of deficiency one and two.

No systematic references to original papers are given except at the end of chap. xx on circuits. As a reason for this the author points out: "in a field which has attracted so many workers, it would be almost impossible to trace the steps by which particular results have reached their present form". Whilst this is quite true, it seems a pity that a few of the more important papers were not mentioned in other chapters so that the reader wishing to pursue his studies further might know where to turn.

Every chapter contains an excellent set of exercises, well graded and of reasonable difficulty. Many of the problems are also supplied with hints for their solution. Valuable guidance in reading is provided in the preface, where also will be found a list of errata, as small typographical errors have not been corrected in all cases.

Statistical Methods for Research Workers. By Dr. R. A. Fisher. Fourth edition, revised and enlarged. Pp. xiv + 307. (Edinburgh and London: Oliver and Boyd, 1932.) 15*s.* net.

THE volume under review is the fourth edition, revised and enlarged, of a "Biological Monograph" first published in 1925. As the editors point out, "Conspicuous progress is now being seen in the field of general physiology, of experimental biology and in the application of biological principles to economic problems". This involves the analysis of large masses of data by statistical methods, in the process of which, solutions to many complex problems have to be sought. Stimulus is thus given to purely mathematical researches, upon which the methods dealt with in the book are based. The aim of the author is to apply accurate tests to practical data by systematically attacking small sample problems on their merits. No attempt is therefore made to prove rigorously the various propositions upon which the theory rests; for these the reader is referred to an excellent bibliography at the end.

In this new edition, greater emphasis is laid on the principle of covariance on account of its increasing use in analysis, and a new chapter dealing with the principles of statistical estimation has been added. There are also provided numerical tables of normal distributions, correlation coefficients, etc., in a form suitable for mounting on the faces of triangular or square prisms.

The monograph is indeed a very valuable contribution to the subject by an acknowledged expert, and should prove exceedingly useful to research workers in the field under survey.

Plasticity: a Mechanics of the Plastic State of Matter. By Dr. A. Nádai, assisted by A. M. Wahl. (Engineering Societies Monographs.) Revised and enlarged from the first German edition. Pp. xxiii + 349. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1931.) 30*s.* net.

IT is not often that one can say, *ex animo*, that a book "fulfils a long-felt want". This is, however, very true of Prof. Nádai's volume, which brings together in a scholarly fashion much scattered information, otherwise difficult of access. The book is divided into two parts. Part I deals with the plastic state of matter with special reference to metals and to mechanical engineering problems, while Part II is concerned with applications of the mechanics of the plastic state to problems of geology and geophysics. The treatment is singularly clear and full throughout, and is built up on a sure theoretical basis in a manner which makes very pleasant reading.

The book is the first of a series of Engineering Societies Monographs published under the auspices of the American Society of Mechanical Engineers. It has been enlarged from the first German edition with the co-operation of the author, and the Publications Committee of the A.S.M.E. is to be congratulated on having made the work accessible to those unacquainted with the German language.

Not only the practising engineer, but also the physicist and geophysicist, will find the volume a very valuable store of information. A. F.

Die Feldspäte und ihre praktische Bestimmung. Von Dr. Karl Chudoba. Pp. x + 54 + 4 Tafeln. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung (Erwin Nägele) G.m.b.H., 1932.) 5 gold marks.

THIS book is intended primarily for the use of the working geologist and petrographer who require accurate but rapid methods of felspar determination applicable to thin sections.

The author has made a wise selection and only those methods are described which give simple and rapid determinations. Twelve pages are devoted to a short description of the general chemical, morphological and optical characters of the felspar group, the remainder of the work being concerned with determinative methods. The main interest naturally attaches to the determination of the plagioclase series, and each method is considered under the headings, "Principal of the Method", "Recognition of the Section", "Determinative Process", "Application of the Method" and "Control of the Determination".

Only the methods suitable for use with the ordinary polarising microscope are considered. Adaptations of these to the Fedorow stage (zonal method of Rittmann) are clearly described but the ordinary Fedorow methods are not treated as they cannot be recommended where speed is an essential. The book is well printed and the figures simple and clear. The text is free from all unnecessary theoretical complications and the book provides an admirable guide to all concerned with felspar determinations.

Almost Periodic Functions. By A. S. Besicovitch. Pp. xiii + 180. (Cambridge: At the University Press, 1932.) 12*s.* 6*d.* net.

THE present book by one of the earliest workers in the subject treated in it promises to become a standard work. In some 190 pages it gives an account of the fundamental theorems dealing with almost periodic functions apart from some special problems connected with differential and difference equations. The first chapter develops the theory of uniform almost periodic functions of a real variable, including the representation by generalised Fourier series and their summation. The second chapter gives various generalisations of almost periodic functions with applications of the Parseval equation and the Riesc-Fischer theorem, topics with which the author is especially familiar through his own researches. The third and last chapter gives an account of H. Bohr's theory of analytic almost periodic functions of a complex variable, their Dirichlet series and their behaviour in and on the boundary of a strip of uniform almost periodicity.

The book, from the abstract nature of its subject matter, makes difficult reading, but will prove most interesting to all those sufficiently well equipped with a knowledge of the theory of functions. It is well arranged and printed in the excellent style associated with the publications of the Cambridge University Press.

The Nidification of Birds of the Indian Empire. By E. C. Stuart Baker. Vol. 1: *Corvidæ—Cinclidæ.* Pp. xxiii + 470 + 8 plates. (London: Taylor and Francis, 1932.) 30*s.*

THE author, fresh from his triumphs of the "Fauna of British India" in eight volumes, has turned his specialist's knowledge to the nidification of the birds, mentioned in his former work. To show how busy the field naturalists have been we mention that the percentage of known eggs has risen from 48 per cent in Oates's work in 1889 to 82 per cent at the present time. The number given to the birds in this volume is the same as the number used in the "Fauna", so that the worker has no trouble in turning up any bird.

In the introduction is given a history of the century of work that has been done on Indian ornithology, with oology not considered until 1864. In 1869 the study of oology may be said to have been begun in a serious way by Hume. It is forty years ago since any book has been published solely on the nidification of Indian birds, so in this volume we again expect the last word on the subject. The author's own collection of eggs, numbering more than 200,000, places him in an authoritative position.

Baker reviews the oology of each species as systematically as possible. Complete breeding area is given, with a description of the place where nesting took place, and the season when eggs are to be found; then a description of the nest and eggs, all full and useful to the worker.

Dielectric Phenomena. 3: Breakdown of Solid Dielectrics. By S. Whitehead. Edited, with a Preface, by E. B. Wedmore. (Published for the British Electrical and Allied Industries Research Association, being Reference L/T. 42.) Pp. 346. (London: Ernest Benn, Ltd., 1932.) 30*s.* net.

THE present volume completes a survey of discharge phenomena in dielectrics. The previous volumes discussed the phenomena which occur in gases and liquids. The experimental evidence is presented first and is followed by a study of the theoretical work that has been published. The author says that when an electric stress is applied to solid insulation, only a small heating current passes initially. As the applied stress increases, the current also increases. At a certain critical value the current becomes unstable. The material can now no longer be regarded as a non-conductor. This sudden fall of resistance is usually taken as the criterion of breakdown. The most noticeable feature in a breakdown is usually the perforation caused in the dielectric, the material being decomposed, fused or volatilised, or the whole three effects may occur together. None of the theories given is very convincing but the author gives a clear presentation of all of them. The work will be helpful to research workers on this subject who are doubtless on the look-out for a theory that fits the experimental data. At the present time the problem appears to be a very difficult one.

The Musk-Rat in Britain

By PROF. JAMES RITCHIE

IN recent months a great deal has been written about the musk-rat in Britain, but too much attention cannot be focused upon its presence and the possibilities of its presence. Besides, a special scientific interest is attached to its story, apart from the economic problems to which it has given rise, for we are watching to-day, from its beginning, the development of an example of the untoward spread and destructiveness of an animal introduced into a new environment, which will take its place with the notorious examples of the brown rat in Europe and the rabbit in Australia.

The interest in the breeding of wild animals for their fur which had been aroused in Europe by the value of the pelts and the success of American experiments, was intensified in Great Britain after the War, since fur-farming, as a new, interesting, and presumably profitable occupation, seemed to offer a way out of the difficulties of unemployment or uncongenial employment. It began with the development of highly specialised breeds of rabbits, led to the introduction of silver foxes for the breeding of which there were already in Great Britain in 1929 thirty-two farms with a stock of eight hundred foxes, and at length brought the musk-rat or musquash (*Odonatra zibethica*). The danger of the arrival of the musk-rat ought to have been foreseen and provided against, for its introduction to the upper valley of the Elbe in Bohemia in 1905 had in twenty years caused serious trouble and entailed much expense throughout great stretches of the valleys of the Elbe and the Danube and their tributaries.

Nevertheless, in 1927, musk-rats were imported for breeding purposes to England and Scotland, and although the value of the imported stock as a rule ensured that in these and later importations care was taken to enclose the animals, in one case at least the musk-rats were turned down on the banks of a stream in order to colonise the area. But whether enclosed or not, musk-rats possess a *wanderlust*, and their habit of burrowing makes them difficult animals to confine by any simple system of enclosure, a fact which was not sufficiently realised in the early days. So that each established colony, except where it was enclosed in escape-proof pens, became a potential centre of distribution. It is said that in the spring of 1931, before the Government had taken any steps in the matter, nearly two hundred people in Britain were keeping musk-rats.

Now it must be admitted, in partial justification of the delayed action of the Government departments concerned, that there was no *certainty* that the musk-rat would thrive under wild conditions in Britain. Central Europe held its warning, but in most of their native haunts in North America musk-rats have shown no undue tendency to increase or spread, nor have the stocks introduced to Finland done so. In the former region, natural control is exercised by carnivorous animals, the mink subsisting very largely upon musk-rats during the winter, while a less share in their destruction is taken by coyotes and lynxes; in the latter region, perhaps unfavourable climate and topography take the place of biological control. In Britain it almost required an experiment to test the possibilities, and such experiments were carried out in the enclosed marshes in which some breeders had liberated their stock. Unfortunately, undesigned experiments came thick and fast owing to escapes, and it was soon apparent that in the absence of biological control, climate and other factors in environment favoured undue multiplication.

Too late in the day to gain an immediately effective hold over the musk-rats in Britain, Parliament passed the "Destructive Imported Animals Act" of 1932, which, with subsequent Orders made by the Minister of Agriculture and Fisheries and the Secretary of State for Scotland, imposed restrictions upon the importation and the keeping of these animals. Since the "Musk-Rats (Importation and Keeping) Order" of March 31, 1932, no licence has been granted for importation, and fourteen licences have been granted for keeping (two of which have become void), under which the animals must be kept in specially constructed pens and must not be kept in the open. On the premises so licensed there are at present about 226 musk-rats. On March 14, a further Order was issued prohibiting absolutely as from April 1, unless Parliament resolves to the contrary, the importation into, and keeping within, Great Britain of musk-rats.

Before the passing of the Act, musk-rats had established themselves in several areas where they have increased and whence they have spread over considerable tracts of country. So that in England wild individuals have been found in Yorkshire, it is said in three of the home counties (Surrey, Kent and Essex) as well as in the Fen district, but the great centre of dispersal has been the Shrawardine Pool, in Shropshire, where on a marshy area of sixty-five acres, two hundred individuals were turned down in an enclosure in 1929, bred freely and, inevitably, contributed a quota of 'escapes'. Radiating from that centre, about seventy miles of the Severn and its tributaries, from Pool Quay to Leighton, have been colonised, and the developments in Montgomeryshire and Shropshire and their immediate surroundings threaten any counties connected therewith by waterways. So far, however, the Ministry of Agriculture and Fisheries has not yet been able to verify any serious case of infestation outside the Severn area, although with so rapidly breeding a creature any local colony may flare up as a new centre of increase and distribution.

In Scotland musk-rats were known to be free in Kincardineshire, the northern limit, although a locality in southern Aberdeenshire has been suspected, and they are said to have been seen at Thornhill, Dumfriesshire, the southern limit, but the main region of infestation lies in the Midlands, in Perthshire and Stirlingshire, where they may be present in any district which is connected by waterways with the River Allan. In the enclosure at Whitemoss Loch, Dunning, there are about a thousand musk-rats. Since the passing of the Act, more than sixteen hundred individuals have been killed in England, and about a hundred in Scotland.

A difficulty in discovering the exact whereabouts of the musk-rats is that of identification on sight, yet it is of the highest importance that their presence or suspected presence should be reported at once to the local authority and the Government department of agriculture. Two British animals are occasionally confused with the musk-rat, the common brown rat and the water-rat or water-vole. Accordingly a photograph of these three species is reproduced (Fig. 1), from specimens in the Royal Scottish Museum, as the simplest means of showing their differences. The first obvious character is size: the musk-rat is larger than either, 22 inches from snout to tip of tail when full-grown, although exceptionally large brown rats have measured 19 and 20 inches. A second characteristic is the long, dense, rich brown fur, the musquash of furriers, composed of a close under-coat and longer glistening guard-hairs, giving the creature a more robust and 'dumpy' appearance than the sleek brown-rat or water-vole. A final safe distinguishing mark is the tail, which, instead of being round, is flat, compressed sideways, and since it is hairless looks and feels like a narrow black razor-strop. A close inspection would show that the hind feet are large and partly webbed.

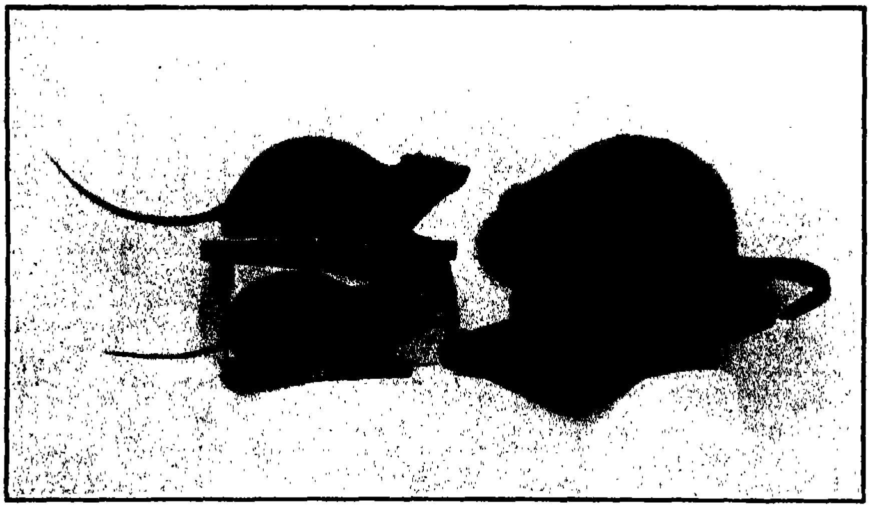

FIG. 1. Right, musk-rat; top left, common brown rat; bottom left, water-vole.

Unfortunately, it is rarely that musk-rats show themselves during the daytime even when they are in numbers, so that other signs of their presence must be looked for. Two of these are illustrated, from Scottish localities; a deep shelter channel cut to give screened access between waterway and feeding ground (Fig. 2), and, most characteristic at this time of the year, the mounds of rushes, grass, leaves and twigs (Fig. 3), which stand three or four feet above the level of the marsh, and are the 'lodges' or joint food-stores and dwelling-houses in which many individuals congregate during the winter months.

The remaining activities of the musk-rat are for the most part invisible, but nevertheless in them lies the great danger of its presence. It lives mainly upon aquatic vegetation, although on the Continent it has damaged green and root crops, and it also eats animal food such as fishes and molluscs; but the loss from these sources is not likely to be very serious. On the other hand, in a country such as Great Britain, with extensive valleys and waterways kept from flooding by natural or artificial embankments, its burrows are a permanent and serious source of danger. The musk-rat is never found at any great distance from water, and in the banks of the streams it frequents it drives multitudes of burrows, since each nest-cavity has its own connexions. The burrows open beneath the water level and the excavated earth is deposited in the bed of the stream, so that unlike the mole's tunnelling, that of the musk-rat leaves no apparent traces. An embankment apparently sound may be honeycombed with cavities, ready to give way on any undue pressure, with what consequences in some localities one can imagine. Here lies another sign of occupation not to be disregarded. Every broken bank in any situation near water should be examined to see if the collapse was due to burrowing, and a distinct musky odour in such place, due to a secretion of the perineal glands of the occupants, should be an aid to identification.

Invisible occupation and spread, extensive undermining of embankments, and a gift of rapid multiplication, for there may be from three to five litters in a year each with six to eight young on an average, combine to make the musk-rat a very dangerous invader.

The danger is realised by many, but it cannot be too widely known. An official of the Canadian Pacific Railway Co. has stated that, in America, apart from damage to canal systems, the creatures "have been responsible for the subsidence of enormous concrete structures, such as head-gates, dams and pool walls, whilst similar timber structures have been completely washed out following the operations of a rat colony in their vicinity" (*Field*, Dec. 17, p. 931, 1932).

What can be done to meet the need of the case? In America musk-rats are easily caught by trapping, and the letter in the *Field* referred to above and another (Dec. 24, p. 966) give excellent summaries of the methods of using traps. But the position in America is a little different; there the musk-rat does no harm in many areas and is an annual source of income, so that the trapper has no wish seriously to deplete the breeding stock. In Great Britain the only aim must be extermination. The departments of agriculture are doing their best, by propaganda against the pest, by the employment of trappers, and by the engagement of Continental experts familiar with the methods employed in Central Europe. These are reported to be confident that "given the men, the means and the time, a properly organised campaign can clear the country". But the condition of Central Europe, with its 100,000,000 musk-rats steadily increasing in numbers and range in spite of every effort, casts some doubt upon the prophecy.

Trapping is necessary but it is not enough, and unconsidered measures run a risk of doing more harm than good. Recently the Ministry of Agriculture and Fisheries advised the destruction of vegetable growths in the Thames, on the ground that the removal of a favourite food would prevent the settling down of the musk-rats and lead to the use of the streams only as highways. But a present need is to restrict the distribution of the animals and to discourage the use of highways to new areas, and, apart from that, the destruction of water weeds is likely to affect seriously the invertebrate fauna and the shelter of the river and, through these, the valuable fish fauna.

FIG. 3. 'Lodge' or joint food-store and dwelling-house.

The Scottish Department of Agriculture, in addition to the employment of trappers, offers a reward of 5*s*. for the killing of musk-rats in certain areas, possibly a useful means of obtaining early information regarding new distribution, and it has tested a mode of destruction which seems to have much in its favour. Trapping is a device against individuals, but in winter the lodges are inhabited by congregations of individuals, which offer a target in the life-history against which every effort of control should be concentrated. The bombing of lodges by miniature bombs, or even the dynamiting of large enclosed areas frequented by many musk-rats, so that they should either be killed outright or disabled by the concussion, ought to be fruitful in results. Any and every reasonable means must now be taken to exterminate this destructive alien, while it is still restricted to a few limited areas. Central Europe points not only to the danger of overwhelming multiplication, but also to the need of devising new and more drastic methods of attack against the pest.

Recent Researches on the Transmutation of the Elements*

By THE RIGHT HON. LORD RUTHERFORD, O.M., F.R.S.

IT is now well established that the change of one atom into another can only be effected by the addition or subtraction of one of the constituent particles of the atomic nucleus, for example, an electron, proton, neutron or α-particle. Such a transformation was first accomplished in 1919 for the element nitrogen by bombarding it with swift α-particles from radioactive substances. About one α-particle in 100,000 comes so close to the nucleus that it enters and is captured by it. This violent disturbance results in the expulsion of a proton with high speed, and the formation of a new nucleus of mass 17. A number of light elements can be transformed by α-particle bombardment in a similar way, and in most cases a proton is ejected.

A new and strange type of transformation was discovered last year by Chadwick: when α-particles bombard the metal beryllium, uncharged particles of mass 1 called neutrons are expelled. These neutrons, which have remarkable powers of penetrating matter, are themselves very efficient agents for the transformation of atoms. Feather has shown that both nitrogen and oxygen are transformed by the capture of neutrons, with the expulsion of a fast α-particle. The types of transformations produced by the neutron are thus very different from those observed with the α-particle. The capture of an α-particle in general leads to the building up of a new nucleus three units heavier than before, while the capture of a neutron leads to the formation of a nucleus three units lighter.

During the past year, Cockcroft and Walton at Cambridge made the important discovery that comparatively low-speed protons are very effective in causing the transformation of a number of elements. The protons are generated in large numbers by an electric discharge through hydrogen, and then speeded up by passing through an evacuated space to which a high potential of the order of 600,000 volts is applied. Under these conditions the protons acquire high speeds comparable with that of the α-particle from radium. When a stream of these swift protons corresponding to a micro-ampere falls on the element lithium, a large number of α-particles are emitted of energy comparable with that of the swiftest α-particle from radium. It seems that about one in 100 million of the protons enters a lithium nucleus of mass 7, and the resulting nucleus of mass 8 splits up into two α-particles, each of mass 4. Cockcroft and Walton have later found that the α-particles emitted consist of two groups differing widely in speed.

This transformation of lithium can be produced at surprisingly low voltages. With strong proton streams, the emission of α-particles can be observed for 30,000 volts; the number of particles increases rapidly with the voltage, and the variation has been examined by different observers over a very wide range, from 30,000 to 1·5 million volts.

Protons are also remarkably effective in disintegrating the light element boron, and again α-particles are emitted. It is possible in this case that the boron nucleus of mass 11, after capturing a proton, breaks up into three α-particles. The radiation observed is complex, and has not yet been analysed in detail. A number of other elements have been found to be transformed, apparently in all cases with the emission of α-particles.

In a special form of accelerating tube devised by Oliphant in the Cavendish Laboratory, a narrow, intense proton stream can be generated at voltages up to 200,000 volts. The protons, after being bent by a magnetic field, bombard a target of about one square centimetre in area. By special arrangements, it has been found possible to obtain in the detecting chamber at least a thousand times the number of particles observed by Cockcroft and Walton at the same voltage. By this method it is easy to observe the particles from very thin films of lithium and boron at comparatively low voltages, while the variation of number with voltage has been measured. For example, a number of α-particles are emitted from lithium with voltages so low as 30,000 volts. α-Particles from boron have been observed at 60,000 volts, but the number increases much more rapidly with voltage than in the case of lithium.

Special experiments have been made to test by this sensitive method whether the heavy elements thallium, lead, bismuth and uranium show any evidences of transformation for 200,000 volt protons, but no sign of emission of α-particles has been observed for these elements. At first, marked effects were observed, but these were ultimately traced to a minute contamination by boron, probably originating in the discharge tube. It seems not unlikely that the effect observed for uranium and lead in the original experiments of Cockcroft and Walton may have been due to an unsuspected contamination by a minute trace of the very active element boron.

During the last few years, much energy has been devoted throughout the world to developing methods of obtaining streams of very swift charged particles with which to bombard matter and effect its transmutation. In the apparatus of Cockcroft and Walton at Cambridge already referred to, a steady potential of 800,000 volts can be reached. A new and simple type of electrostatic generator has been designed by Van der Graaf and Atta in the Massachusetts Institute of Technology, with which they have obtained a steady potential of

---

* Substance of the Friday evening discourse delivered at the Royal Institution on March 10.

1·5 million volts, and a larger apparatus is under construction with which they hope to obtain a potential of 15 million volts to apply to a large vacuum tube. Brasch and Lange have applied high momentary voltages to a discharge tube by using an impulse generator.

A new and ingenious method of multiple acceleration has been devised by Lawrence of the University of California with which he has already obtained protons of energy 1·5 million volts by using a potential less than 10,000 volts. The transformation of lithium has been examined at this high energy using a proton current of about a thousandth of a micro-ampere. It is hoped to develop this method so as to obtain protons of energy as high as 10 million volts or more.

Even if these new projects prove successful, the speeds of particles produced by their aid are much smaller than those observed for the very penetrating radiation in our atmosphere, where electrons and protons of energy from 200 million to 2,000 million volts are present. From the experiments of Anderson in Pasadena and Blackett and Occhialini in Cambridge, it seems certain that these very swift particles are very efficient in causing the transformation of nuclei, probably in novel ways. Strong evidence has been obtained of the production of a new type of positively charged particle which has a mass small compared with that of the proton. This may prove to be the positive electron, the counterpart of the well-known negative electron of light mass.

Obituary

DR. C. A. BARBER, C.I.E.

WITH the passing on February 24 of Charles Alfred Barber is severed a link with the past, for he belonged to that old school of scientific investigators who were the first to turn their attention to the problems lying behind development in tropical agriculture. When he gained his first acquaintance with it, there was an awakening to the fact that a harvest does not necessarily follow planting. In the East, Ceylon had gained experience from coffee; in the West, Harrison and Bovell had pointed the way to a healthier growth of cane.

This, as yet dim, appreciation of the need for investigation, led to Barber's first appointment in 1891 as superintendent of agriculture in the Leeward Islands where, however, his stay was brief, for the post was abolished in 1895. In 1898 he was appointed Government botanist, Madras, and, as director of the Botanical Survey of Southern India, commenced to complete the flora of southern India. But here, as in the West Indies, the need for investigation of the economic crops was slowly gaining recognition and his attention was soon diverted to the study of cane and crops in general. These were the days before the Royal Commission of 1896 had led to the establishment of the Imperial Department in the West Indies and before the organisation of an agricultural service in India. It is to Dr. Barber, not least among the pioneers of this period, and to the practical benefits of his work, that the present-day scientific worker in this field largely owes his security in a firmly established service scattered throughout the tropical parts of the British Empire.

During this earlier period, Barber found time to carry out a detailed investigation of the haustoria of sandal and other plants for which he was awarded, in 1908, the degree of Sc.D. of the University of Cambridge. But the earliest economic problem to receive attention was that of the sugar cane disease which was creating anxiety in Madras. In 1912, when the Cane-breeding Station was opened at Coimbatore, the selection fell on him for the post of sugar cane expert, and his field of investigation was extended to cover the whole of India. The problem that faced him was unique. The main cane tract of India lies outside the tropics where, for climatic reasons, the plant forms no viable pollen. Seedlings had to be raised outside the tract and no mean questions of testing and introduction were raised. There was the further fundamental question of the parental type to be used to impart the resistance to frost and drought necessary for success. Through a detailed study of the Northern Indian canes he was attracted to Katha, a hardy Punjab cane, and its similarity to *Saccharum spontaneum*, the wild Kans. He was led to use this wild plant as one parent and, by crossing it with a Noble cane, raised seedlings of which Co.205 remains as testimony to his originality of thought. In its wider aspect his study led him to a classification of the Indian canes, to which he ascribed a dual origin. Again it is a tribute to his insight that this classification, based on a morphological study, has required so little modification from the later Dutch cytological investigations.

Original, too, was Barber's recognition of the importance of the root in the economy of the plant and of the need for a detailed study of the root system. For his services to India he was created a C.I.E. in 1919 on retirement and, in 1931, was awarded the Maynard Ganga Ram prize for Indian research.

Born in 1860 at Wynberg in South Africa, Barber came to England at the age of ten years. After five years' service in the Manchester and Liverpool District Bank, he entered Christ's College, Cambridge, of which he became a scholar. In 1889 he was appointed University demonstrator in botany and, before proceeding to India, served on the staff of the Royal Engineering College, Coopers Hill, where he succeeded the late Prof. H. Marshall Ward.

PROF. JOHAN VAN BAREN

By the death on February 7 of Prof. Johan van Baren, agricultural science has lost the leading authority on soil mineralogy. Born in Rotterdam on April 18, 1875, van Baren became assistant in mineralogy to Prof. J. L. C. Schroeder van der Kolk, of the University of Delft, in 1899. In 1903 he went to Wageningen, where he taught mineralogy and geology at the Agricultural College, and when this College was made an Agricultural University, in 1918, he was appointed professor of mineralogy, geology and agro-geology.

When van Baren went to Wageningen, his facilities for teaching and research were of the most meagre kind, but in the thirty years he spent there he built up a department for his subject which at the present time has no equal. The museum and library, to which he devoted much attention, are particularly fine.

Besides his University work, van Baren had interests in many societies. He was one of the founders of the Geological Society of the Netherlands and Colonies, of the Society for Studying the History of Mathematical and Physical Science, and of the Wageningen section of the Dutch Natural History Society. He was for many years on the Committee of the Royal Dutch Geographical Society, and was a corresponding member of the French Academy of Agriculture. In the International Society of Soil Science he was an active member. He contributed papers to various conferences of the Society and took part in the preparation of the Soil Map of Europe. He devoted much attention to the soils of the East Indian Archipelago, and raised the Junghuhn Fund for the study of these soils.

Van Baren's principal work was a handbook, "The Soil of the Netherlands", in the preparation of which he was occupied for more than twenty years: altogether he published more than a hundred scientific papers. He was particularly interested in the Quaternary deposits of Holland and their correlation with the glacial phenomena of the Alps and Scandinavia. He also studied recent volcanic deposits of the East Indian Archipelago. In soil work he specialised in detailed mineralogical studies, and published a series of memoirs treating of the soils of Holland and the East Indian Archipelago (issued from the Geological Institute of the University of Wageningen). More recently he devoted particular attention to the problems of origin and development of limestone soils under the very contrasting climatic conditions of tropical and temperate regions. In pursuance of his studies he travelled extensively both in Europe and the East.

Van Baren was an inspiring teacher. The writer has vivid and pleasant recollections of an excursion to South Limburg with him and his students in the early summer of 1926—busy days spent in field work, meals taken together at one long table in the hotel at Valkenburg, and discussions and amusements in the evenings. The best of good fellowship existed and when the day's work was done, van Baren joined in the students' concerts with the same enthusiasm as he showed in leading the excursions. A vigorous man of kindly personality, he will be greatly missed by his friends and colleagues in soil science in other countries as well as Holland.

W. G. O.

MR. F. P. BURCH

We regret to announce the death on February 11 at the age of thirty-three years of Mr. Francis Parry Burch. He was the second son of the late Prof. G. J. Burch, F.R.S., of University College, Reading, and was a scholar of Winchester and of Gonville and Caius College, Cambridge, where he took the Natural Science Tripos, Part II (Physics) in 1922.

Burch joined the staff of the Research Department of the Metropolitan-Vickers Electrical Co., Ltd., Manchester, in 1922 as a member of the newly-formed Physics Section, devoting much of his time to the problems of heat transmission, and in the early days of the radio industry he made a careful study of the characteristics of filaments for receiving and transmitting valves. With the development of apparatus for producing electrical transients of extremely short duration, it became necessary to extend the existing facilities for recording these transients, and in conjunction with Mr. R. V. Whelpton he constructed the first high-voltage cathode ray oscillograph in Great Britain. To put the recording of high voltage transients on a sound basis, Burch made a careful study of the theory of the potential divider, completing this valuable work by constructing an apparatus to record transients up to one million volts. Burch then turned his attention to the continuously evacuated power transmitting valve and rectifier, and was largely responsible for the successful completion of a 30 kw. screened grid valve and master oscillator operating at a wavelength of 10 m., the first high power four-electrode valve in the world.

By his death the Metropolitan-Vickers Co. has suffered a great loss, and is robbed of one of its most charming personalities.

We regret to announce the following deaths:

Dr. John Belling, cytologist in the Department of Genetics of the Carnegie Institution of Washington, an authority on the structure of chromosomes, on February 28, aged sixty-six years.

Prof. G. C. Bourne, F.R.S., emeritus professor of zoology and comparative anatomy in the University of Oxford, who did much work on tropical marine fauna, especially on the formation of coral atolls, author of a "Text-Book of Oarsmanship" published in 1925, on March 9, aged seventy-one years.

Dr. R. T. A. Innes, formerly Union Astronomer in South Africa, known for his discoveries and records of binary stars, on March 13, aged seventy-one years.

News and Views

Sir Frank Dyson, K.B.E., F.R.S.

A large gathering, representative of the Admiralty, the Board of Visitors to the Royal Observatory, the staff of the Observatory, the Royal Astronomical Society and the British Astronomical Association, attended a complimentary luncheon to Sir Frank and Lady Dyson on March 10. Affection and respect for the human and lovable chief of astronomy, and for his attainments and achievements, were the note of the letters read from those unable to be present and of the speeches of Prof. F. J. M. Stratton and Dr. W. A. Parr, the presidents respectively of the Royal Astronomical Society and the British Astronomical Association. Tributes were paid to the unselfish yet competent manner in which Sir Frank Dyson has sunk himself in the work of the Royal Observatory during his tenure of the office of Astronomer Royal and to the friendly and helpful way in which he has co-operated with his astronomical colleagues, professional and amateur alike. The best of wishes for the future were expressed to both Sir Frank and Lady Dyson.

Prof. J. Proudman, F.R.S.

Prof. J. Proudman, the present holder of the chair of applied mathematics in the University of Liverpool, has been elected to the chair of oceanography in the University which has become vacant by the death of Prof. James Johnstone. Prof. Proudman joined the staff of the University in 1913 as lecturer in mathematics, and has held the chair of applied mathematics since 1919. In 1919 he was appointed director of the newly founded Tidal Institute and director of Liverpool Observatory. He is a member of the British National Committee for Geodesy and Geophysics and of its sub-committee for Physical Oceanography. He is also a member of the British Section of the International Committee on the Oceanography of the Pacific. He has served on many committees concerned with tidal matters and inundations. His own researches have mainly been concerned with the dynamical aspects of ocean tides and their currents and with the action of wind and of variable atmospheric pressure upon the sea. For his work on these subjects Prof. Proudman was awarded a Smith's Prize of the University of Cambridge in 1915 and the Adams Prize in 1923.

The Californian Earthquake

The earthquake that occurred in southern California at 5.54 p.m. on March 10 (1.54 a.m., March 11, G.M.T.), though it was the cause of considerable loss of life and property, can scarcely be regarded as one of the great earthquakes of that State. The number of persons known to have lost their lives is 151, and it is estimated that 7,500 houses were destroyed or damaged, and that the value of the property lost was more than ten million pounds. Most of the places in which houses were injured lie within an area about sixty miles long, running in a south-easterly direction from near Los Angeles to beyond Santa Ana. The place that suffered most is Long Beach, a town on the coast about twenty miles south of Los Angeles. Here, 65 persons were killed and about a hundred wounded. The epicentre thus lies near the coast, possibly under the ocean, so that the earthquake cannot be connected with the great San Andreas rift, which, in this part of California, runs about fifty miles inland. Since 1769, the Los Angeles district has frequently been visited by severe, though not disastrous, earthquakes. About ninety miles to the west lies Santa Barbara, part of which was seriously damaged by the earthquake of June 29, 1925.

Soviet Expedition to the Pacific Ocean

The expedition to the Pacific Ocean organised under the joint auspices of the State Hydrological Institute and the Ichthyological Institute of the U.S.S.R. has recently returned from the Far East. The expedition made a detailed investigation of the Sea of Japan, the Sea of Okhotsk and the Bering Sea, in which thirty-one members of the Hydrological Institute took part. In the Sea of Japan a thorough investigation was made of the region stretching from the border of Korea to the Gulf of Olta. For the first time in the history of oceanographic research, detailed work was carried out in the parts adjoining the Gulf of Peter the Great at a depth of 8,500 m., and at that depth various organic forms of life hitherto unknown to science were discovered. It has been ascertained that the sharp descent of the coast-line —at an angle of 24°—forms a huge ravine overgrown with tree-shaped corals. One such coral was extracted by the expedition. Samples of the sea-bed at a depth of 8,400 m. have been obtained, and also much hydrological material which makes it possible to determine, according to the seasons, the annual hydrological system of the region of the Gulf of Peter the Great.

Certain inaccuracies of existing maps have been corrected. In some places the depth was found to be 1,000–1,500 m. instead of 100 m.; elsewhere, on the contrary, submarine ridges have been discovered in place of depressions. Much material on hydrology has been collected which point to the penetration of the waters of the Pacific Ocean to the eastern part of the Sea of Okhotsk. In the Bering Sea, hydrological and biological investigations were made, in some places at a depth of 3,800 m. For the first time, the interchange of the water masses of the Bering and Chukhodsk Seas during the summer season was investigated. Numerous measurements were made by the expedition which will enable a more exact map to be made of the western part of the Bering Sea.

Metallurgy Building at University College, Cardiff

In Nature of August 5, 1915, an account was given of the new building which had been erected for metallurgy at University College, Cardiff. An important extension to this building, which completes the scheme, was formally opened on March 16 by Mr. W. D. Woolley, chairman of the Monmouthshire and South Wales Coalowners' Association. The new accommodation provides: ground floor, mechanical laboratory, physical laboratory and lecture room; first floor, three research laboratories, private room, museum and library; second floor, chemical laboratory, balance room, combustion and gas analysis, laboratory and private room. The College has now a well-planned and well-equipped building for teaching and research work, the erection of which is due to the generosity of the Monmouthshire and South Wales Coalowners' Association.

Projected Flight over Everest

IN our issue of February 4 (p. 160), reference was made to the two aeroplanes which have been modified to undertake a flight over Mount Everest. According to the Karachi correspondent of the *Times*, the machines arrived at Karachi on March 9. The main base for the expedition will be Purnea. The photographic results of the flight, should it be successful, are likely to be of considerable interest, for nothing is known at present of the south face of Everest. Indeed, if the photographs are available in time, they may be of assistance to the expedition now in India preparing to climb the mountain (NATURE, Jan. 7, p. 10), especially if the snow and ice conditions have changed considerably since the 1924 expedition. Useful data may also be obtained of atmospheric conditions; while we know a good deal about the atmosphere at 30,000 ft. above mean sea level, it is likely that conditions at this absolute height but with high mountains below will be different. The aeroplanes, however, are not suited for making useful cosmic ray observations. The flight will be a great adventure, for should the machines have to come down through engine failure, the chances of finding a suitable landing place in that great area of mountainous country are small.

Discovery of Sexuality in Plants

THE discovery of sex in plants is usually credited to Camerarius (1694), and Koelreuter (1761) is generally believed to have made the first systematic study of plant hybrids. Statements of Sachs in his "History of Botany" are mainly responsible for these attributions. Dr. Conway Zirkle is able to show, however (*J. Hered.*, vol. 23, No. 11), that other names really have priority in connexion with these important developments in the history of science. N. Grew, in an address to the Royal Society in 1676, expressed the view that the stamens are the male organs of a flower, the pollen acting as vegetable sperm. Thomas Fairchild, whom Sachs referred to as "a gardener in London", was in fact the leading experimenter of his generation, and his famous cross between sweet william and the carnation is shown to have been made at least as early as 1717. Philip Miller was the first to describe insect pollination by observations on tulips. This was not, however, in 1751, as stated by Sachs, but so early as 1721. He also observed natural crossing in cabbages as well as sexual reproduction in cucumbers and melons. Dr. Zirkle also gives an interesting account of equally early American observations on pollination and crossing, chiefly in maize, by Cotton Mather (1716), Judge Dudley (1724) and Governor Logan (1735). A letter of John Bartram in 1739 shows that he too had made species crosses in *Lychnis* at that date.

Courtship of Birds

THE courtship displays of birds, wherein they manifest the amorous emotions which possess them, are now daily becoming more and more assertive. Much has yet to be learned concerning the 'behaviour' of birds thus possessed at this time; and the relation of this behaviour to various and often conspicuously coloured plumage, wattles, bare skin, or inflatable air-sacs. The pheasants afford striking illustrations of apparently conscious effort to display such ornaments to the best advantage before apparently disinterested females. The belief that these displays serve as aphrodisiacs must be regarded as well-founded. This fascinating aspect of bird life can now be studied at the Zoological Gardens, Regent's Park; a number of tragopans, or horned-pheasants, as well as Cheer, Impeyan, and Kalij-pheasants, having just been added to the collections. Blyth's tragopan from Assam, and the crimson tragopan from the south-eastern Himalayas, each bears an erectile appendage over the eye, of a vivid blue colour; and an inflatable wattle at the throat. In Blyth's tragopan this is yellow tinged with blue, while in the crimson tragopan it is orange, barred with blue, and when filled with air presents a strange effect. If the courting antics of the tragopans be compared with those of the golden and Amherst pheasants, wherein the chief ornaments take the form of a great frill of vividly coloured feathers encircling the neck, the contention that both types display deliberate and purposeful movements designed to make the most effective possible use of these ornaments will seem incontrovertible. Though the Darwinian view that these resplendent areas were brought to perfection by the selective preferences of the female, before whom they are displayed, has lost its hold, they are nevertheless instances of 'sexual selection'; since only the most amorous males, the most skilled performers, can succeed in arousing the desired response in their phlegmatic prospective mates.

Vanished Races in South Africa

FROM time to time news is received of the discovery in South Africa of a new and previously unknown culture, presumed to be the work of a vanished race. More often than not the finds are associated with stone-work or the evidence of metal-working. The latest discovery to be reported (*Times*, March 13) comes from the northern Transvaal, where Mr. D. S. van der Merwe, assistant registrar of mining titles on the Rand, has discovered sacrificial graves of an entirely new type, a sacrificial altar, approached by ceremonial causeways and by staircases, an irrigation system of enormous extent, together with the remnants of a large dam. There is also a copper tool, which is said to be an authentic mining implement. These finds are ascribed to a vanished race, and on account of the diminutive size of the stairways, it is suggested that its members were pygmies. The collections have been placed at the disposal of the Ethnological Department of the University of the Witwatersrand and are said to be regarded by the Department as very important. As Mr. van der Merwe is a layman in ethnological matters, the verdict of experts in the cultures of the natives of South Africa will be awaited with interest. As a rule, unfortunately, previous claims to the discovery of new cultures and vanished races have not survived their impartial scrutiny.

A New South African Culture?

A CLAIM to have distinguished a new material culture in South Africa is put forward by Dr. Ir. E. C. N. Van Hoepen, director of the National Museum, Bloemfontein (*Argæologiese Navorsing*, Dl. i St. 5), in describing a remarkable stone pipe from a shelter near Bethlehem. Its peculiarity lies in the ornamentation, a system of curved grooves and on one side a sinuous ridge ending in a reversed E, representing a snake. Similar pipes have previously been described, one of clay from the ash-heaps of stone huts at Vegkop by Van Riet Lowe and another of stone by Stow. Van Riet Lowe attributed the pipe he described to the Leghoya, dating the huts at about 1790, but Dr. Van Hoepen does not consider his reasoning or evidence satisfactory, and points out that stone huts are not a characteristic of Bantu culture, the Leghoya themselves using conical grass thatched huts, according to Stow. He himself sees in the pipes and the shelters closer affinities with Hottentot, Bushmen, and Xosa, but concludes that the three characters, the stone pipes, the stone huts and the ornamentation do not belong to any known African culture. We are, therefore, he holds, dealing with something new, a culture for which the name 'stone-hut' culture is proposed. This view, important as it is for the history of South African cultures, should be accepted with some caution. Its confirmation by further evidence will be awaited with interest.

American Archæologists in Yugoslavia

AT a meeting of the American Anthropological Association held in Atlantic City at the end of December, Dr. Vladimir J. Fewkes described the work during the past summer of a joint archæological expedition of the Peabody Museum, the Fogg Art Museum, Harvard University, and the American School of Prehistoric Research in Jugoslavia. Some 150 archæological sites were visited and examined. A large proportion of these were found to belong to Greek, Roman, Macedonian or Byzantine cultures. The most considerable undertaking of the expedition was the excavation of the neolithic site at Starcevo, of which the investigation had been begun in the previous year. The settlement is dated at about 2500 B.C. and is found to consist of a number of irregularly placed groups of semi-subterranean dwellings, of which the foundations have been exposed. Among the material found are crude but well-made cooking pots, painted pottery, needles, awls and spatulas of bone, stone knives and celts, shells, and small libation tables of baked clay. The settlement was one of small farmers with domesticated animals, who supplemented their food supply by hunting and fishing. In a report of the communication from Science Service, Washington, D.C., Dr. Fewkes is said to have stated that the expedition had gathered fresh evidence relating to the early trade routes of this part of Europe, an area he regards as the archæological key-region of the Balkans.

Spectrum Analysis

THE increasingly great interest now being shown in spectrum analysis is well exemplified by two recent developments in the United States. The first of these was the setting up by the American Society for Testing Materials of a committee (E-2) on spectrographic analysis in its application to analytical and metallurgical problems. This committee is now at work and it is probable that tangible results will be forthcoming in the near future. News of the second development has just reached Great Britain. It has been decided that one of the lines of work to be intensively pursued at the magnificently equipped spectroscopic laboratory of the Massachusetts Institute of Technology is the application of spectrum analysis to industrial and related problems. In order that as close touch as is possible may be made with industrial problems, a research conference is to be held at the Institute during the week beginning July 17, and it is hoped that at this conference industrial experts, academic research workers and manufacturers of spectroscopic equipment will meet and discuss those aspects of the problem with which they are individually familiar. It is clear that one of the earliest developed aspects of spectroscopy is again coming very much to the fore, and that the dreams of some of the early spectroscopists regarding the general use of this technique in industry are coming measurably nearer realisation.

Machine Age's Starvation Predicted

THE comparatively rapid depletion of the earth's available resources in this mechanical age was considered by Prof. R. A. Gortner, of the University of Minnesota, in a paper before the American Association for the Advancement of Science in December (Science Service, Washington, D.C.). It is pointed out that irreplaceable stores of natural resources absolutely essential to modern industrial civilisation are disappearing into the 'maws of industry' and so are wastefully dissipated over the earth. While the publicity of technocracy directs attention to the part played by mechanical energy in remaking economic conditions, the shelves in some of Nature's cupboard are showing signs of exhaustion of the materials necessary for a mechanical age. In particular, Prof. Gortner mentions the approaching exhaustion of copper, antimony, tin, lead, zinc, chromium, manganese, nickel and iron, which are stored in parts of the earth accessible to man. The rate of use of some of these metals is doubling each decade. We still use tin-foil for wrapping up sweets and cigarettes. At the present mining rates, iron will be exhausted in Germany in about fifty years and in the United States in about a hundred years. The supply of sulphur in the United States will fail in fifteen years, the coal of Germany in less than a thousand years and of the United States, notwithstanding its huge lignite deposits, in less than fifteen hundred years. It looks as if the machine age may starve to death before long, a victim of to-day's profligate use of metals, coal and oil. Water power, alcohol from vegetation, solar energy, etc., are at present totally inadequate to replace oil and coal. Will future civilisations look back upon the industrial civilisation of the twentieth century as an age of robbery?

U.S. Bureau of Standards

The annual report of the Director of the Bureau of Standards (Government Printing Office, Washington, 1932) shows the trend of scientific developments during last year. The increase in the industrial applications of very low temperatures has made it advisable to extend the scale downwards from −100° C. to −259° C. and a temporary scale covering this range has been established. Fire tests have been made on the new welded steel floors which are now being used in buildings. They consist of steel floor plates welded to beams spaced two feet apart. Tests were made with fire both above and below the floor. Gas appliances found quite satisfactory at sea level develop defects when used in cities at high altitudes. The causes of these defects are being investigated. Perhaps the most spectacular advance made during the year has been to increase the accuracy of the primary frequency standard to one part in ten million. Regular transmissions of standard high-frequency waves at a frequency of 5,000 kilocycles per second are broadcast every Tuesday for four hours. The accuracy obtained is one cycle per second, that is, one part in five million. The ionised layer in the atmosphere has been determined to be the major controlling factor in the long distance transmission of radio waves. The measurement of the height of this layer is of primary importance in interpreting transmission conditions and increasing our knowledge of radio wave transmission. Using improved equipment, these measurements were made on one day in each week throughout the year. An automatic recorder is now in use which makes continuous measurements. Useful work is done in making careful analyses of samples of ores, alloys, pure metals, cement and pure chemicals. These samples are sold to industrial laboratories and are used for checking their own methods and results. This plan has contributed greatly to the precision of the analytical work in these laboratories and the project is self-supporting.

Miners' Nystagmus

Two reports on this subject by a Committee of the Medical Research Council were issued in 1922 and 1923. The principal finding of the Committee was that the chief symptom of this disease—the involuntary oscillation of the eyeballs—is caused by an insufficiency of the light reaching the eyes of the miner while at work, and that the most important measure of prevention is to secure for the miner at work adequate illumination. Nevertheless, in spite of considerable improvement in the illumination of mines, the incidence of the disease has, on the whole, steadily increased, for compensation on account of this disability was paid to 10,638 persons in 1930; this is the largest number, with one exception, during the past twenty-three years. The Medical Research Council has therefore considered it advisable to reconstitute the Committee, which has now issued a third report on the subject (Special Rep. Series, No. 176. H.M. Stationery Office. 9*d*.). This reaffirms, in the strongest terms, the conclusions of the former committee. There should be constant illumination of 0·25 foot-candle on the coal face, and it is understood that there are recent developments in the direction of improving illumination in mines. To account for the continued prevalence of the condition, it must be recognised that the oscillation of the eyeballs is but a part of the disease, and various psychoses and neuroses are also present. The practical treatment of the disease should consist in the elimination of a hopeless dependence on compensation by the provision of opportunities for work of some kind, even if restoration of full work underground has to be preceded by a period of work in daylight.

Guard Posts for Road Island Refuges

Illuminated guard posts or 'bollards' are now gradually coming into use on all types of roads which carry fast vehicular traffic. In the *Osram G.E.C. Bulletin* for February, a description is given of a well-designed guard post which should prove useful not only by indicating the refuge to pedestrians, thus prompting them to cross the road at that point, but also to motorists; thus removing a frequent cause of accidents. It is a luminous pillar 4 ft. high, the light being emitted only from the side which faces the traffic. The back of the pillar is made of solid steel tube, so that in the event of a smash the damage done will be probably much less than if it were made of cast iron. The head of the bollard is arranged as a lantern with the red glass fixed around half its circumference. The red glass is generally illuminated by a sixty-watt lamp but sometimes a small auxiliary lamp is used as well so as to prevent a complete 'black out' if the main lamp is extinguished. Complete isolation of the bollard from the electric supply in the event of damage is easily obtained by opening a door near the ground level where the time-switch and fuses are fixed.

Researches on Sedimentation

The report of the Committee on Sedimentation for the two years 1930–1932 has been published under the auspices of the Division of Geology and Geography of the U.S. National Research Council as National Research Bulletin No. 89, 1932 (pp. 229, price

1 dollar). The report is by the chairman, Prof. W. H. Twenhofel, who contributes a general introduction, and various committee members and others, who are responsible for many valuable records of original research and abstracts of literature on the accessory minerals of igneous and sedimentary rocks. Special attention deserves to be given to the paper on the classification and terminology of the pyroclastic rocks by C. K. Wentworth and Howel Williams. The Bulletin also includes papers on recent advances in the study of peat; recent marine sediments; settling of bentonite in water; relation of the buffer mechanism of sea water to the solubility of calcium carbonate; modern marine sediments in California; bacterial and chemical factors in lime deposition at Tortugas, Florida; varved sediments; chert and flint, concretions, and cone-in-cone; abrasional work of river ice and of glaciers; ground water hydrology in its bearing on sedimentation; rôle of micro-organisms in sediments; accessory minerals of crystalline rocks; and glacial sediments. In addition, there are summaries of work on sedimentation carried out at Stanford University, and also of recent work by German and British investigators; and abstracts of the literature on accessory minerals of igneous rocks and of sedimentary rocks.

Developments in Market Gardening

THE report of the recent conference on "Recent Developments in Market Gardening" held at Rothamsted contains a great deal of information which is not readily available in a collected form. Two of the classical market garden areas, the Bedfordshire early potato and brussels sprouts district and the equally well-known spring cabbage, brussels sprouts and fruit area of Evesham are treated in detail from the point of view of the practical grower, and the subject is also considered from the point of view of the canner, whose part in the industry is becoming increasingly important. In recent years market gardeners have found their province invaded by large-scale farmers, who have in part substituted vegetable growing for the less profitable crops of their ordinary rotation. These men, whose methods form the subject of one of the papers, have several advantages not possessed by the smaller cultivators; plentiful animal manures, large-scale mechanical methods, and a possibility of converting unsaleable surplus into live stock products. The reply of the genuine market gardener has been to move towards greater intensification, and to retire into districts as yet inaccessible to large-scale methods. The conference as a whole leaves the impression that abundant production of market garden crops is relatively easy to secure. It can in fact be an embarrassment, and every additional outlet whether by preservation, more economical distribution, or the education of the public taste, needs careful investigation. Copies of the report, price 2*s*., can be obtained from the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Institute of Industrial Administration

IN a pamphlet recently issued by the Institute of Industrial Administration, 47 King William Street, E.C.4, outlining its objects and examinations, it is stated that management in industry is essentially the exercise of administrative function and involves the control and co-ordination of the technical functions. The operation of the administrative function does not vary greatly from one industry to another despite differences in the application of some of the technical functions, especially that of production. It is admitted that personality is a highly significant factor in industrial administration but training serves both to develop and inform personality. To the average individual upon whom industry has mainly to rely, training may make all the difference in his efficiency, to his own advantage and that of the nation. In preparing a revised syllabus of examinations, the Institute has endeavoured to collate the principles and practice bearing on the functional aspects of industrial administration. The scheme consists of three stages—fundamentals, intermediate and final—the first of which presents in elementary form a general idea of how an industrial undertaking is conducted and its relation to external affairs. In the intermediate and final stages the subjects of the fundamental stage are extended and amplified.

Physics at Harvard

VOL. 21 of Contributions from the Physical Laboratories of Harvard University consists of separate copies of the papers by members of the staff and other research workers which have appeared in the *Physical Review*, the *Proceedings* of the National Academy of Sciences and of the American Academy and other periodicals during 1930–31. There are forty of them, which differ considerably in type and area of the letterpress, but are all cut to pages 9¼ in. × 6¾ in. Their subjects extend over almost every branch of physics and they testify to the catholicity and quality of the research work done at Harvard. The completion of the new research laboratory and the improvement of the Jefferson Laboratory during the period covered by the volume afford a suitable opportunity for a 47-page illustrated description of the present buildings and equipment, and a short history of their foundation and of the work done in them, and in the Cruft Laboratory. Nearly 130 men have carried on research in the laboratories during the last thirty years and many of them now fill chairs of physics in American universities.

Mining Facilities in South Australia

ACCORDING to the annual report of the Director of Mines and Government Geologist of South Australia for 1931, an amending act was passed during the year concerning principally mining upon lands, beneath which mineral substances had been alienated prior to the adoption of the principle of reservation of such substances. The act protects land-owners, but under certain conditions allows prospectors to enter such lands under reasonable conditions; the responsibility for seeing that such an authority is not given to an undesirable character is placed upon the Warden.

Anatomy of the Tortoise

THE attention of teachers and students in vertebrate anatomy who include the tortoise in the list of the animals they study by dissection, is directed to an account of the anatomy of that animal published by the Royal Dublin Society (vol. 20, No. 28, Dec. 1932). The late Dr. J. Stuart Thomson was engaged on the preparation of this memoir over a number of years with the view of providing an account of the principal structural features of the tortoise for his own and other senior students. The descriptions, in about eighty pages, of the external characters and the various systems of organs are systematic, clear and adequate, and are supported by twenty-five well-drawn plates. This useful paper is published at the reasonable price of 8*s*.

Land Utilisation Survey

THE second annual report of this survey of Great Britain records that thirty-one counties are now completed or very nearly completed, comprising nearly 8,700 sheets. More than a third of the area of the country is covered by these maps. Compared with the previous year, progress has been rapid. Thirty-six counties, during the last year, have undertaken work for the survey and there are now only four counties in which nothing or very little has been done, namely Essex, Carmarthen, Argyll and Perth, but considerable help is still needed in the West Riding of Yorkshire outside the completed Sheffield area. The director of the Survey also asks for the assistance of volunteer workers in the counties of Somerset, Westmorland, Wiltshire, Peebles, Inverness and Sutherland. Work on the reduction of the results to a scale of one inch for publication is proceeding actively on several sheets in England and Scotland, including Cromer, Ipswich, Ullapool and Liverpool.

Announcements

PROF. P. Debye will deliver the fifteenth Faraday lecture before the Chemical Society on March 29, at 5.30, at the Royal Institution, Albemarle Street, W.1. The lecture will be entitled : "The Relations between Stereochemistry and Physics".

THE memorial fund instituted in memory of Dr. R. Stenhouse Williams, formerly director of the National Institute for Research in Dairying (University of Reading) to which reference has already been made in our columns, has now reached a total of £1,800. It is proposed to close the fund shortly, but further contributions will be welcomed. The fund will be used for the advancement of dairy science at the National Institute for Research in Dairying.

A SERIES of five talks by Mr. Charles Elton, director of the Bureau of Animal Population at the University of Oxford, on "Exploring the Animal World", will be broadcast by the British Broadcasting Corporation on Friday evenings commencing on April 21. During these talks, co-operation will be sought between the amateur observer and scientific worker, especially in the second talk on "Woodland Life", when listeners will be asked to help in a survey of the birds of different kinds of woods all over England.

WITH reference to the note on "Illuminated Fountains" which appeared in NATURE of March 4, p. 302, Mr. A. S. E. Ackermann has pointed out that an article by him on an illuminated fountain at the Barcelona Exhibition appeared in the *Journal and Transactions of the Society of Engineers* (21, No. 3, 115 ; 1930). In this fountain there were 750 incandescent lamps of 2,500 candle-power, besides arc lamps. Photographs of the fountain in action are reproduced.

WE regret to learn that a serious error occurs in the description of the 'soil conductivity bridge' by the Cambridge Instrument Co., Ltd., advertised in the Supplement to NATURE of March 11, p. iv. This should read : "This A.C. Bridge will measure directly the specific resistance of samples of soils ; the reciprocal of the reading being taken as the specific conductivity in mhos per cm.^{3}. The range is from 1 to 100,000 ohms, or 1 to 10^{-5} mhos." The term 'mhos' (reciprocal ohms, measuring conductivity) was altered without authority by the printer to 'ohms', after the proof had been passed for press by the advertiser.

MESSRS. HOPKIN AND WILLIAMS, LTD., 16 Cross Street, Hatton Garden, London, E.C.1, have issued a useful booklet of 60 pages, price 1*s*., entitled "Organic Reagents for Metals", in which working directions are given for the use of sixteen organic reagents, such as picrolonic acid and quinalizarin, which have become important in analytical chemistry in recent years. Improved details are given for some of the methods, and a comprehensive bibliography is appended for each reagent.

APPLICATIONS are invited for the following appointments, on, or before, the dates mentioned :—A registered medical practitioner with experience in bacteriological research for the Ministry of Health—The Director of Establishments, Ministry of Health, Whitehall, S.W. (March 27). An assistant lecturer in bacteriology in the Edinburgh and East of Scotland College of Agriculture—The Secretary, 13 George Square, Edinburgh (April 7). A principal investigator for the Burden Mental Research Trust—The Secretary of the Trust, B.M.A. House, Tavistock Square, London, W.C.1 (April 10). An independent lecturer in materia medica and pharmacology in the Welsh National School of Medicine—The Secretary, Welsh National School of Medicine, The Parade, Cardiff (April 25). A woman assistant demonstrator in physics in the Royal Holloway College (University of London), Englefield Green, Surrey—The Principal (May 10). An assistant lecturer in mechanical engineering in the Battersea Polytechnic, London, S.W.11—The Principal.

Letters to the Editor

Scientific Centralisation in the British Empire

THE leading article entitled "Ottawa and After", in NATURE of October 8, 1932, concludes with an interesting comment on higher education in the Dominions. I can speak with first-hand knowledge of conditions in New Zealand and Australia, and feel that there is a greater fundamental difficulty than the existence of a superior climate which is more conducive to outdoor life. The difficulty is an Imperial one. The Empire is centripetal, not centrifugal, and the tendency is to look to England as the only place where the best may be encountered, or the best work carried on. This influences educational outlook from the secondary schools to the universities, and the public, despite crudely nationalistic tendencies on the parts of some lesser journals, sees greener pastures in all branches of culture, in distant Albion.

Add to this the fact that Dominion universities are primarily concerned with professional training, in the present stage of development of these lands, and it becomes clear that the inducement to attract and retain good men in professional posts involves more than might be supposed. The old-established scientific societies with all their tradition and prestige, their facilities for publication and criticism of original work, and their influence in paving the way to higher posts, are in Great Britain.

The personal contacts made and maintained at meetings of the societies are of inestimable value in fanning the flame of original work. Just as the 'hungry forties' were the driving force in colonisation, so the underpayment of university assistants in the nineteenth century led them to posts in Australia at salaries far beyond their reach for many years had they remained in England and Scotland. But, just as it has become safer for the workers to remain in England, so is it with the professor's assistant, who now cannot be so readily induced to accept a professorial salary of £1,100 in Australia, with a sacrifice of the advantages of scientific centralisation, advantages greatly enhanced by the establishment of medical and industrial research subsidy under the ægis of the scientific societies.

It has long been my conviction that it rests with the better men of the Dominions themselves to save the outer Empire from the intellectual anæmia which highly centralised intellectual advantage and prestige must necessarily provoke. After their post-graduate years in England they must resist the almost overwhelming temptation to accept posts in the British Isles, and must, when opportunity offers, return and fight their lonely battle for its own sake.

Unless and until this happens our claim to Imperial greatness must remain open to question, for otherwise all our technical and governmental skill will have been directed to purely material ends, and the term 'Commonwealth of Nations' must remain a hollow sham.

The Oldoway Human Skeleton

WE should be grateful if the following statement on the question of the age of the Oldoway human skeleton could be published in NATURE.

One of us (L. S. B. L.) brought back to England a large series of samples of the different strata which were collected not only from the region of the 'man site' but also from widely separated points, up and down the Oldoway Gorge. These samples have now been examined at the Imperial College of Science and Technology by P. G. H. Boswell and J. D. Solomon. The following conclusions emerge from their study.

(1) The materials of Beds II and III appear to be very similar to each other so far as their mineral constitution is concerned, but they can both be clearly distinguished from the materials of Bed IV and also from Bed V.

(2) The material of Bed V is so distinctive in its mineral content that it can be immediately distinguished from any of the four lower beds.

(3) Thin layers of steppe-lime, which in places occur at the base of Bed V, are not distinguishable with certainty from the steppe-lime which forms the top part of Bed V.

(4) The thin red-coloured deposit which is present in the section of the 'man site' overlying Bed II and underlying Bed V is a hillwash material in which the characteristic minerals of Beds IV and V occur.

(5) Samples of Bed II, actually collected at the 'man site', at the same level and in the immediate vicinity of the place where the skeleton was found, consist of pure and wholly typical Bed II material, and differ very markedly from the samples of the matrix of the skeleton which were supplied by Prof. Mollison from Munich.

Following from (4) above, it is clear that erosion had removed from the region of the 'man site' the whole of the overlying Beds III and IV before the hillwash, formed during the last stages of this process, was deposited and afterwards covered up by the formation of Bed V. Thus, at some stage before the deposition of Bed V in this area, the top of Bed II was exposed as a land-surface with a thin mantle of hillwash material.

We may further note that all of those who have examined the section at Oldoway are agreed in the opinion that the Oldoway skeleton cannot reasonably be regarded as having been buried after the deposition of Bed V proper, and of the steppe-lime which covers it.

One of the reasons which caused one of us (P. G. H. B.) in his letter in NATURE of August 13, 1932, to suggest a post-Bed V date, was the presence of small pieces of steppe-lime in the matrix sent from Munich. He was not then aware, however, of the presence of steppe-lime below Bed V, as mentioned in (3) above, so that there is now no necessity for upholding this view.

In order that the important question of the age of the skeleton shall be established on as sure a foundation as possible, the evidence outlined above will be supplemented by the results of a further examination, by Reck and his colleagues, of rock collections from Oldoway and the volcanic highlands to the east. Meanwhile, on the basis of the evidence summarised above, it seems highly probable that the skeleton was intrusive into Bed II and that the date of the intrusion is not earlier than the great unconformity which separates Bed V from the lower series. On the other hand, it seems certain that the skeleton was deposited where it was found before the main mass of Bed V and the overlying steppe-lime were formed, that is, the skeleton appears to have been buried at the time of the existence of the old land surface connected with the steppe-lime at the base of Bed V.

It so happens that there is other and independent evidence which supports this view. On this old land surface, and also in the basal deposits of Bed V, there was found an industry which has very close affinities with the phase C of the Upper Kenya Aurignacian. From the work at Gamble's Cave in 1929, we know that the men of this culture-stage buried their dead in the contracted position, as was the case with the Oldoway skeleton. It seems likely, therefore, that the Oldoway man was one of the race which made the tools that are found on the old land surface and in the basal deposits of Bed V.

The above views accord with those of Mr. E. J. Wayland, director of the Uganda Geological Survey, summarised in letters to NATURE (October 15, 1932) and *East Africa* after his visit to Oldoway last August.

Heights of Nuclear Potential Barriers and Nuclear Structure

I RECENTLY pointed out in these columns[1] that experimental evidence indicates that the heights of the potential barriers of the light nuclei are proportional to the atomic number. This simple relation can be shown to fit in with Heisenberg's suggestion[2] that nuclei are composed of protons and neutrons and that there is an attractive force $J(r)$ between neutron and proton at close distances, and between neutron and neutron $K(r)$, the former being the greater. An α-particle contains two neutrons and two protons, a nucleus contains n_1 neutrons and n_2 protons; there will therefore be an attractive force between nuclear neutrons and α-particle protons *and* nuclear protons and α-particle neutrons, superposed on the Coulomb repulsion between protons. Thus we have (neglecting the neutron-neutron force $K(r)$, since it is less than $J(r)$):

$$V = \frac{2n_2e^2}{r} - \frac{2n_1k}{r^p} - \frac{2n_2k}{r^p}$$

for the potential at a distance r. I have assumed a law of force of the form $\frac{k.\, n_1.\, \text{no. of protons}}{r^p}$ to represent $J(r)$.

This gives

$$V = \frac{2n_2e^2}{r} - \frac{2k(n_1+n_2).}{r^p}$$

It happens that for the light elements n_1 is very nearly equal to n_2, never differing by more than one unit. Thus we have approximately,

$$V = \frac{2n_2e^2}{r} - \frac{4kn_2.}{r^p}$$

This gives for V_c the maximum when $dv/dr = 0$ the value

$$V_c = \frac{2n_2e^2}{(2pk/e_2)^{1/(p-1)}}\left[1 - \frac{1}{p}\right]$$

If p is constant, that is, if the law of force is the same from element to element, we have that V_c is a straight line function of n_2, which is what is found experimentally.

The critical radius for the height of the barrier is $(2pk/e_2)^{1/(p-1)}$ and has, for elements for which n_1 is approximately the same as n_2, a constant value; this would be expected, because both repulsive and attractive forces increase linearly with the nuclear charge. This critical radius does not necessarily govern the volume of the nucleus. An accurate measurement of the barrier heights would afford a means of testing the truth of the assumption made by Heisenberg (and necessary to his theory of nuclear stability) that the neutron-neutron force is less than the neutron-proton force; since if it were not so, the attractive force would depend on n_1 alone, giving different values for those elements (such as lithium and beryllium) for which n_1 does not equal n_2.

The heights calculated for these two elements (both subject to considerable error) do fit in better with an attraction proportional to $n_1 + n_2$ than to n_1. It is interesting to note that the attractive force in the case of a proton does depend on n_1 alone, so that the barrier height to a proton should be rather higher than half that to an α-particle for light elements: for heavy elements, where the number of neutrons is roughly twice the number of protons, the barrier will not rise so rapidly; perhaps this accounts for the relative ease of penetration of heavy nuclei by fast hydrogen ions.

Since the slope of the line relating height and nuclear charge depends on p, the index power of the law of force, it should be determinable from this relation.

Arc Spectrum of Iodine

THE analysis of the spectrum of the normal iodine atom has proved relatively difficult, partly because of the wide multiplet separations, and partly because of the transitional nature of the coupling characteristics. Some constant intervals, due to Turner[1], have long been known, and S. F. Evans[2] in 1931 presented a partial analysis which included most of the stronger lines in the region 4700–10000 A. Recently S. C. Deb[3] has published a more extensive analysis, which differs very materially from that of Evans. As he dismisses the latter's results rather summarily, with the remark that they are "mainly incorrect", some observations on his paper may be of assistance in forming a just appreciation of the present position in regard to this question.

In the first place, it may be noted that of the 160 wave-lengths listed by Deb, 75 are identical with those given by Bloch[4] and 19 with those of Evans, although the text implies that they are his own determinations. Further, Bloch classifies all but 9 of these 75 as spark lines, and Evans's observations (unpublished), together with those of Wood and Kimura[5], are in good general agreement. The multiplets proposed take no account of this heterogeneity of the data, including arc and spark lines on an equal footing. It is therefore not surprising that the multiplet intervals show much wider discrepancies than should be permissible by reason of wave-length inaccuracies. As one instance we may take the interval 1459·3 cm.$^{-1}$ which was well established by

Evans on the basis of five values lying within a range of 0·3. Deb's values for this vary from 1451·6 to 1459·5, with a mean of 1455·5. It is clearly essential in work of this kind, first to obtain a homogeneous set of data of the highest possible accuracy, and secondly to accept as significant only those intervals which agree within the order of accuracy of the data. The work under consideration fulfils neither of these requirements.

Again, the evidence obtainable from hyperfine structure work[6] is entirely neglected by Deb, and in fact is only in occasional agreement with his allocations of *j* values, although it is in harmony with Evans's observations.

Finally, Deb's value for the ionisation potential, 10·548 volts, is open to serious question. It is based on a very doubtful interpretation of an emission continuum with a maximum at 3406 A.; this is presumably that commonly known by the wavelength 3460 A. of its less refrangible edge. He attributes it on very slender evidence to the capture of an electron by an iodine atom in the $5p^4.6s.{}^2P_{\frac{3}{2}}$ state. The evidence against this interpretation need not be detailed here, but it is of a very convincing character. Although several Rydberg sequences are given they do not lead as usual to independent values of the ionisation potential, since the term values involved are based on the above assumption; neither can they be regarded, in view of various objections to them which can be raised, as affording any support to that assumption.

In view of these criticisms I am bound to say that our knowledge of the structure of the iodine spectrum does not appear to have been sensibly advanced by the paper under consideration.

Line Absorption of Chromic Salts in Relation to Co-ordination

THE absorption spectra of salts of trivalent chromium are characterised by exceedingly narrow bands in the red part of the spectrum. Their presence in the spectra of co-ordination compounds of chromium was discovered by Lapraik[1] in 1890, whose work is the more remarkable for being completed prior to Werner's theory of co-ordination valency and therefore at a time when the peculiar structure of the compounds was unknown.

We have recently examined the aqueous solutions of a number of chromic compounds by means of a spectrometer and have noticed a very simple fact which would doubtless have been missed had we used a spectrograph. In the case of every compound studied, only *one* narrow band is sufficiently strong to be detected by visual observation of dilute solutions in short observation tubes. In many cases it is as persistent as the neighbouring broad 'molecular' absorption band, for on dilution both disappear at about the same concentration. For convenience we shall refer to this narrow band as the 'characteristic band' of the compound.

An interesting relationship has been established between the chemical constitution of a complex ion and the position of the characteristic band. It is evident from the accompanying table that as the three electrically neutral molecules of ethylene diamine (en) in $[Cr(en)_3]^{+++}$ are successively replaced by negatively charged oxalate radicles, the band moves farther into the red. The position of the characteristic band of a complex ion is sensibly unaffected by the accompanying anions or cations.

Molecular Ion	Approximate Position of Characteristic Band.
$[Cr(en)_3]^{+++}$	6705 A.
$[Cr(en)_2 C_2O_4]^{+}$	6845 A.
$[Cr(en)(C_2O_4)_2]^{-}$	6915 A.
$[Cr(C_2O_4)_3]^{---}$	6970 A.
$[Cr(H_2O)_6]^{+++}$	6695 A.

The condition of chromic ion in violet solutions of the simple salts is, presumably, $[Cr(H_2O)_6]^{+++}$, and the nearness of its characteristic band to that of $[Cr(en)_3]^{+++}$ is noteworthy. When a solution of chromic sulphate is boiled, sulphate ions displace water molecules from the complex and the green colour is thought to be due to $[Cr(H_2O)_4 SO_4]^{+}$. We find the characteristic band of the green solution appears, much broadened, at about 6820 A., which is in qualitative agreement with this point of view. Similar results have also been obtained with green solutions of chromic chloride in which one or more chloride ions have entered the co-ordination sphere.

We consider that the bonds uniting ethylene diamine and oxalate radicles to chromium are predominantly, though not purely, covalent, since all these complex ions can be resolved into pairs of optical isomers[2]. The presence of extremely narrow bands in their spectra is at first sight surprising, since such bands are usually associated with electron transitions in free ions, as for example, those of certain rare earth metals[3]. However, the phenomenon is quite in harmony with Linus Pauling's 'model' of the molecular ion[4], for *even when co-ordinated*, chromic ion possesses three unpaired electrons and it may be supposed that the absorption of a quantum of red light produces an excited state in which the spin moments of two of the electrons cancel one another, the multiplicity being thereby reduced from four to two. Thus arises the possibility of pure electron transitions in a covalently linked molecular ion. On the other hand, the co-ordination compounds of cobaltic ion contain no unpaired electrons and no unoccupied 3*d* levels, so electron transitions of the type described above are clearly impossible. Certainly we have been unable to discover any narrow bands in the absorption of $[Co(en)_3]^{+++}$, $[Co(C_2O_4)_3]^{---}$ or $[Co(CN)_6]^{---}$ within the visible spectrum.

Mycorrhiza in the Genus *Citrus*

RECENT experiment points to a close and direct correspondence between the incidence and character of mycorrhizal infection and differences in the rooting medium. In view of the existence of mycorrhiza as a regular phenomenon in many crop plants, it appears likely, therefore, that intensive study of the soil conditions controlling its development may be a matter of practical importance to growers.

Although experimental research in the hands of a few specialists has yielded and continues to yield remarkable results for certain specialised groups, ignorance is still profound in respect to the significance and control of the widespread and apparently relatively unspecialised mycorrhiza known as the 'Phycomycete type'[1]. Recorded in an immense number of wild herbaceous species belonging to the most diverse families and from the most varied habitats, and also in a few trees, mycorrhiza of this kind has been observed in certain crop plants of economic importance; for example, strawberry[2], sugar cane[3], wheat[4], and the lychee[5]. It is of some interest, therefore, to place on record its existence in the genus *Citrus*; both in the sweet orange, *C. sinensis*, and the sour orange, *C. aurantium*, in the orchards of southern California. Previous records for the genus from Italy are fragmentary and unsatisfactory[6].

The roots of the cultivated orange are remarkably poor in root hairs, especially when grown in the neutral or alkaline soils of California. As observed in roots of trees from the experimental field plots at this Station, there is a regular and quite characteristic distribution of mycelium bearing large 'vesicles' in the young roots, involving inter- and intracellular infection with periodic digestion of the intracellular system of hyphæ and their contents.

Since oranges and other citrus fruits are cultivated under highly artificial conditions in California and elsewhere, it will be of interest to learn whether there is a similar type of root infection in the species used as stocks when growing wild in their native habitats.

The practical significance of the problem lies in the importance of nitrogenous manures in *Citrus* culture in California, where some form of this element is practically the only fertiliser employed. Experience has shown that nitrogen supplied as sodium nitrate or similar inorganic compounds gives poor results, whereas sodium nitrate treatments combined with stable manure or rapidly decomposable organic matter in the form of cover crops are highly beneficial.

No adequate explanation of these differential results has yet been offered, and the discovery of this type of mycorrhiza suggests that the organic materials supplied to the soil furnish appropriate food for the root fungus and provide the conditions requisite for root infection, a proportion of the metabolised products passing eventually to the root cells during the regular and extensive digestion of intracellular mycelium.

The application of pure culture methods to the problems presented by the mycorrhizal habit has proved the existence of mutualistic relations of fundamental importance in the economy of the vascular hosts, and older theories respecting the nutrition of mycotrophic plants must be reviewed and tested in the light of modern experimental methods. In the case of *Citrus*, carefully devised experiments and comparative observations on roots of trees subjected to different kinds of manuring in orchard plots should provide evidence of the correctness or otherwise of the hypothesis outlined above.

In view of the heavy cost of manuring in Californian orchards and the inconsistent responses shown by the trees, it is clearly of importance to ascertain whether different treatments and results can be related directly and invariably with the condition of the roots in respect to fungus infection.

Number of Mendelian Factors in Quantitative Inheritance

IN a note in the current *Eugenics Review* entitled "Evolution by Selection", "Student" has directed attention to some statistical consequences of the inheritance of quantitative characters, in relation to the theory that these are due to the cumulative effect of a number of ordinary Mendelian factors.

"Student" refers in particular to the remarkable selection experiment carried out by F. L. Winter[1], in which a commercial variety of maize was exposed to mass selection from year to year in two diverging lines for high and low protein, and in two more for high and low oil content. For protein the initial value was about 11 per cent with a standard deviation of a little more than 1 per cent, but in the average of the last three years the mean of the high selection line is 16·82 per cent while that of the low selection line is less than half that value, namely, 7·53 per cent. The aggregate change produced by selection in both directions is thus 9·39 per cent, or more than nine times the original standard deviation.

With respect to variability, it may be noted that the high line now varies from 13·4 to 19·8 per cent, while the extremes for the low line are 5·7 and 10·5 per cent; so that the two lines are now separated by a considerable gap, and therefore cannot possibly have any single genotype in common. The variability of the low selection line has shown a slight tendency to diminish, and that of the high selection line a slightly greater tendency to increase, so that no general tendency to a decrease in variability ascribable to selection is to be observed; thus, there is no reason to think that the selective potentialities of the material have been appreciably exhausted in producing the great modification which has been brought about.

"Student" contrasts these well-substantiated facts with the belief, widely held among geneticists not so many years ago, that the selection of small differences (fluctuations) can only lead to unimportant evolutionary effects. They may also be contrasted with the oft-repeated statement that selection can do no more than select the best of the existing variety of genotypes, and with the commonly taught belief that the diversity available for selection is easily exhausted, from which it is inferred that evolutionary progress must wait upon the occurrence of mutations. It was, indeed, often represented as consisting in these occurrences.

The results obtained with oil-content have been even more striking; for the high oil line now contains nearly six times as much as the line selected for low oil content, and differs from it by more than twenty times the original standard deviation. "Student" uses these data, together with reasonable estimates of the intensity of selection, to obtain an estimate of the least possible number of factors which must be postulated to obtain the results up to the date of the report; he concludes that at least 100–300 factors would be needed; and, taking into account the complete lack of evidence that selection is nearing its limit, considers that it is more probable that the actual number of factors is measured in thousands.

Estimates of the number of factors needed to explain quantitative inheritance are beset with considerable difficulty, and "Student" has admitted to me in correspondence that his calculation fails from over-simplification. Other well-established phenomena in maize, however, such as the flood of recessive defects revealed by every plant which has been used to found a selfed line, combined with the inevitable rarity of each of these defects, taken individually, in the population from which the foundation plant was selected, force one to the conclusion that all commercial varieties must be segregating in hundreds, and quite possibly in thousands of factors influencing the normal development of the plant. This emphatic experience, has, I believe, killed among maize breeders all those doctrines concerning the supposed inefficacy of the selection of minute differences, with which the teaching of modern genetics was at first encumbered.

It should be emphasised that the result of importance for evolutionary theory is not that the number of factors must be very large, thousands for example, rather than hundreds, but the direct demonstration that selection has the exact effects that selectionists have ascribed to it, without the limitations by which its action has been supposed to be restricted, on the strength of an early misapprehension as to the number and variety of the Mendelian factors exposed to its cumulative action.

Fourier Analysis and Vowel Curves

IN NATURE of December 24, p. 965, Prof. E. W. Scripture discussed difficulties in applying Fourier analysis to recorded vowel curves, and he published two illustrations of the latter. The second of these, or at least what the corresponding curve would have been if the process of ground noise suppression had not been used in the recording, is strikingly similar to a curve I once drew up to illustrate complex modulation of a carrier wave in radio. The 'interior waves' correspond to the carrier wave, and the regular repetition or pattern corresponds to the so-called 'modulation envelope'.

This suggests that an alternative method of analysis, the applicability of which to a vowel curve similar to that published might repay investigation, would be to consider the vowel curve as that of a 'carrier note' undergoing modulation, the modulation being not necessarily sinusoidal but perhaps more complex. For example, the 'modulation envelope' of the published curve approximates to a saw-tooth form.

This method of analysis might not really be an alternative to Prof. Scripture's method, and might only be an alternative method of stating the latter. An artificial 'vowel curve' corresponding to saw-tooth modulation or other arbitrary modulation would make an interesting test of Prof. Scripture's and of other methods of analysis. Incidentally, such an artificial vowel curve could fairly easily be recorded and reproduced, and the electrical equivalent of it could be generated and reproduced directly without recording.

It may be worth while considering the bearing on these considerations of the fact that a modulated wave may be analysed into a carrier *plus* side-bands. A wave form approximating to a 'saw-tooth' modulated carrier can be constructed out of the carrier and a small number of side bands, all undamped waves. The general appearance of such a wave form would be similar to that of the vowel curve published, and therefore would afford (though in this case erroneously) just as strong grounds for holding that the wave form was inconsistent with analysis into undamped waves and that it required an analysis into damped waves.

The point which emerges from this is that Fourier analysis is not the only analysis into sinusoidal components. Consider a sinusoidally modulated carrier represented by $A(1+k\sin\overline{pt+\alpha})\sin\omega t$. If the carrier frequency, $\omega/2\pi$, is much greater than the modulation frequency, $p/2\pi$, the resulting wave form *seems* to be periodic at frequency $p/2\pi$, because the modulation envelope is periodic at this frequency. Close examination of the curve, or mathematical examination of the formula, shows, however, that the carrier waves in one cycle of the modulation frequency are situated differently with respect to the modulation envelope from those in another cycle, there being a phase difference. Unless ω is a multiple of p, the wave is not periodic at frequency p, and unless ω and p are commensurate there is no true period at all. Fourier's analysis is therefore not applicable, but this does not prove definitely that analysis into sinusoidal components is not possible.

Photography of Faint Transient Light-Spots

PROF. H. HARTRIDGE in his letter in NATURE of January 21, expresses the need for "A lens having a numerical aperture of 0·8 or 0·7, a focal length of 25–50 mm. and adequate definition on the film over an area of 3–5 mm." It is perhaps not commonly noticed that a Mangin lens-mirror out of a motor-car headlight has just about this specification. I have used such a mirror to photograph a cathode ray oscillogram. The definition, though not what one would desire, was yet good enough to be useful.

Apparently there is no other commercial type of optical system that has both the large numerical aperture and the long focal length required, together with passable definition; but I should be glad to be corrected. The tiny image of an achromatic substage condenser was spoilt by scattering in the emulsion.

Some Mangin mirrors are purposely made with considerable spherical aberration on the axis, of a type thoroughly described by A. C. W. Aldis[1]. This aberration can, I find, be very simply corrected by placing a block of glass, having plane parallel faces, so that the rays converging from the mirror traverse the block and form the image on its outer surface. The principle is the same as that of the correction of the aberration of a microscope objective by using a coverslip of the correct thickness. But the thickness required is very much greater. By piling up plates, I find that 4·8 cm. of crown glass, $\mu_D = 1{\cdot}51$, is just right for an old naval mirror marked "5·25 ins. optical focus". The block does not make the coma worse, and only slightly increases the colour aberration. In a photograph taken with this system working at a numerical aperture of 0·5, point-objects appear as disks 1 mm. in diameter. This holds over an area of about 1·5 cm. diameter on the photograph. The merit of this arrangement of a mirror and block is its cheapness. Better, but presumably costly, lenses for photographing faint objects have been described by Rayton[2], also by McLennan and Ireton[3].

Constitution of Vitamin C

IN a recent communication[1] Micheel and Kraft have proposed a structure for ascorbic acid of a furane-carboxylic acid type. This structure was considered by us some months ago, and although attractive as explaining many of the chemical properties, we did not put it forward, principally on the ground that it would not satisfy the crystallographic requirements; these are, briefly[2], that the pseudo-symmetry, optical properties and the thinness of the molecule demand a structure which is almost completely flat. Unless the disposition of the carbon valencies in ascorbic acid is entirely novel, a molecule of the structure proposed by Micheel and Kraft would certainly not meet these requirements. These objections, which were considered in detail by us before the publication of our previous note[3], still hold, and they apply also to variants of Micheel and Kraft's structure containing ethylene oxide or pyranose rings.

Substituted βγ-Diphenyladipic Acids and Derivatives of Chrysene

PROF. R. ROBINSON and Mr. G. R. Ramage in a recent letter[1] state that they are engaged in the synthesis of certain substituted βγ-diphenyladipic acids and of certain derivatives of chrysene. I have been working in this field for some years and work in progress, or projected, in part in collaboration with research students, includes the synthesis of substituted βγ-diphenyladipic acids derived from *o*-, *m*-, and *p*- chloro-, bromo-, iodo-, hydroxy-, methoxy-, nitro-, amino- and dimethylamino- benzaldehyde and from veratrole and piperonal via the benzylidene malonic esters[2] and cinnamic esters[3] with the object of (*a*) effecting the optical resolution of both forms, (*b*) their conversion into derivatives of chrysene[4], and (*c*) their conversion into derivatives of possible therapeutic and industrial value. The research on the reduction of substituted cinnamic esters has been assisted by grants from the Chemical Society in June 1930 and 1931.

Wave Equations and the Conservation of Energy

IN Dirac's "Quantum Mechanics" the "equation of motion" satisfied by any observable ξ not involving the time explicitly is

$$(i\,h/2\pi)\,\dot{\xi} = \xi H - H \xi$$

where H is the Hamiltonian. The conservation of energy, when H does not involve the time explicitly, is deduced from this by putting $\xi = H$, giving $\dot{H} = 0$.

Another fundamental assumption of Dirac's theory is his form of wave equation, which imposes another condition on H. He points out that it is legitimate to assume the quantum conditions only for one particular time and then investigate whether they hold for all time, but a similar limitation, which appears to hold for the wave equation, seems to have been overlooked. The condition that the wave equation may hold for all time leads to an equation which expresses the conservation of energy. We thus have two conditions that it seems desirable a wave equation should satisfy, leading to the conservation of energy and charge.

It is known that the second condition is satisfied by Dirac's linear equation and also by Schrödinger's non-relativistic equation, but not by the second-order relativistic equation. I have proved (in the course of work not yet published) that the first condition also is satisfied in the same two cases. These facts seem to provide a stronger reason for rejecting the second-order relativistic equation than those usually given.

Band Spectra of Barium Oxide (BaO)

IN the flame of the arc between carbon electrodes containing barium chloride or nitrate, a class of red-degrading bands appear between λ 4300 – λ 8000. These have been attributed to the oxide of barium and analysed into two systems with their (0,0) bands at 17,713 ν and 16,060 ν respectively. The rotational structure analysis of (0,1), (0,2) and (1,1) bands for the less refrangible system and (1,0), (0,0), (0,1) bands for the more refrangible system have been done. The two systems have a common lower level, and are due to $^1\Sigma$, $^1\Sigma$ transitions. In the lower state, $B'' = 0{\cdot}3075$ cm.$^{-1}$. The detailed account of the analysis will appear elsewhere.

Heathen Baptism in Early Britain. A communication from Miss Eleanor Hull in *Folklore* (vol. 43, pt. 4) brings together evidence from various sources bearing on the existence of baptism as a pre-Christian rite in Britain. The fact that it is found in Wales, where Scandinavian influence was small, seems to point to the fact that it had an independent origin in these islands and was not introduced by Norse or Danes. Among the Scandinavian races, pre-Christian baptism, as the sprinkling of the child with water which accompanied the bestowal of a name, was an integral part of the Asa creed. It established a bond between baptiser and baptised, sometimes constituting the latter the heir of the former. The Norse practised lay baptism without religious ceremony; but in Ireland a regular rite, at which Druids officiated, was carried out. Aillil Olum, who succeeded to the throne of Munster early in the third century, was baptised by the Druid who foretold the marriage of his father Eoghan and by his prognostication fixed the propitious day of the marriage. The 'heathen baptism' is also mentioned in the Irish version of "The Travels of Sir John Mandeville" in connexion with the circumcision of Isaac and Ishmael. The tales of the Mabinogion give several instances of heathen baptism, as for example in "Pwyll, Prince of Dyved" and in "Math, Son of Mathonwy". Scottish folk-tales give fewer examples; but in the story of "The Knight of the Red Shield" the knight, it is prophesied, shall be unbaptised "until he shall come to an island and strike a crag of stone on a man". In the Fenian tales baptism is taken as a matter of course by the heroes; and it is considered by Dr. J. A. MacCulloch that the Scottish custom of dropping three drops of water on the forehead of a child immediately after birth is a relic of the rite of pagan baptism.

Ancestor Spirits among the Nuba. Mr. D. Hawksworth, in recording some observations among the Nuba of Southern Kordofan (*Sudan Notes and Records*, vol. 15, pt. 2), deals with the cult of ancestral spirits and its relation to the spiritual and secular headship of the social group. The veneration, almost amounting to worship, of the ancestral spirit is the basis of their religion, their exceptional tribal patriotism, their reluctance to leave the home of their ancestors, their reverence for the elders, and so forth. All communications are addressed, not to God, but to the ancestral spirit, and from it come all punishments for sin. Communications to the ancestral spirit are made through the *kujurs*, tribal priests, the mediums of the ancestral spirits, who seize upon them on occasion and throw them into a trance. The office of *kujur* is not hereditary, as the spirit may seize upon anyone; but as a rule, especially in a family group, the ancestral spirit seizes one of the offspring of the deceased *kujur*. *Kujurs* fall into two categories: the great *kujurs* who are seized by the spirit of the original ancestor of the tribe, and the lesser *kujurs* of the family group, who generally specialises in some branch of culture. The great *kujurs*, except in certain tribes which have kings, are the patriarchal heads of the tribe, exercising both spiritual and secular powers. They are entitled to the slaves and booty taken in war, they receive the bride-price of female orphans, and when a male orphan has no family head, they pay the bride-price on his behalf. The *kujur* makes the necessary communications and offerings at stated times to the ancestral spirit, and receives tribute on his behalf. The office is not confined to males; but when a female *kujur* is appointed, her husband immediately runs away.

Stork in Western Europe. Press notices on the Continent frequently state that the white stork (*Ciconia ciconia*) is becoming scarce in western Europe and that its final disappearance is probable. But the stork has never been very common in western Europe, where, as a bird of Asiatic origin, it is at the limit of its range. Nevertheless, according to Jan Sokolowski, the progress of civilisation, particularly as shown in the draining of marshes, has made more difficult the life, and still more difficult the multiplication of storks, so that in some districts of Germany their numbers have been reduced by as much as 60 per cent. The protection of the stork now in force throughout Germany had become necessary, and that it has been efficient is evident from the latest reports, which state that the number of nests in Eastern Prussia has risen to 9,200. In Poland, east of the Vistula, storks are more numerous than in western Europe and the appearance of birds in greater numbers of nesting pairs makes it certain that there the stork is in no danger of extermination (*Ochrona Przyrody*, Warszawa, 12, p. 1, 1932).

Fauna of Hot Springs in North America. In the summers of 1923, 1927 and 1930, Charles T. Briers visited hot springs in the Yellowstone National Park, and in the adjoining States of Utah, New Mexico, Nevada, California and Idaho for the study of their fauna. The present paper is his third on the subject (*Proc. Amer. Acad. Arts Sci.*, 67, No. 7, 1932). In such thermal springs special limiting factors are associated with the abnormally high temperature of the water, the highly variable hydrogen ion concentration, and the variable salinity, which is comparable to that of brackish water. The adaptation to high temperature extends over a narrow range of 5°–20° C., as the animals live at temperatures of 40°–60° C. instead of at 30°–40° C., which is the upper limit of existence for the majority of terrestrial and aquatic animals alike, including pœcilothermic and homœothermic types. As to how the peculiar adaptations of the hot springs' fauna arose, the author is uncertain: perhaps naturally resistant forms were selected, perhaps the constitution of the species has changed towards greater heat-resistance, perhaps the simpler forms are relics of a primordial fauna which has always lived at high temperatures, but the last case is not very likely.

Chromosome Numbers in Vertebrates. Attention may be directed to a useful list of chromosome numbers in vertebrates, compiled by Messrs. K. Oguma and S. Kakino (*J. Genetics*, vol. 26, No. 2). Many of the earlier counts in birds and mammals were clearly much too low, due to clumping and inadequate fixation of the chromosomes. Twelve appears to be a common haploid number both in fishes and amphibians, 11 also being found in certain fishes and toads. Several recent papers conclude that in reptiles, as in birds, the male is XX as regards its sex chromosomes, the female being the heterozygous sex. In general, the chromosome numbers in reptiles are higher than in amphibia, where 12 is the commonest number. Disregarding the earlier and inaccurate counts, the numbers in birds are high in the few species in which a critical study has been made, for example, 38 in the duck, turkey and fowl. Among mammals the numbers are relatively low in marsupials ($n = 6$ to 11), although some of these numbers may require revision upwards. In other mammals they appear to range so high as $n = 43$. As regards man, the $2n$ number 48 and the presence of an XY pair in the male has recently been confirmed by Minouchi and Ohta.

Temperature and Seed Germination. A review by Thos. I. Edwards of great interest to seed-testing laboratories has recently appeared (*Quart. Rev. Biol.*, 7, No. 4, 428–443, 1932) entitled "Temperature Relations of Seed Germination". The conception of the term 'optimum temperature for germination' is shown to be capable of several interpretations, which are discussed in the paper. The minimum and maximum temperatures for germination are also investigated. Many instances where seeds of wheat and other plants have started to grow on ice are given. The highest temperature of germination seems to be that of *Pinus rigida* at 57° C. The paper contains much interesting information about the behaviour of various seeds at different temperatures, but its main result is apparently a vindication of the generally accepted standards of temperature at present employed by seed-testing stations.

Ultra-Violet Light and Fungi. The effect of ultraviolet light on various species of *Fusarium* has recently been studied in detail by Alice A. Bailey (*Bot. Gaz.*, 94, 225–271, 1932). Rays from a quartz mercury vapour lamp were directed on to agar cultures through suitable ultra-violet transmitting screens which were used as the lids of the respective culture dishes. Irradiation always slowed up the radial growth of a culture as compared with a control in ordinary light, and often the growth appeared zoned or had other physical differences. The colour of *Fusarium* colonies was often altered as a result of the influence of ultraviolet rays. The most pronounced effect was in the substitution of microspore for macrospore formation in many species. Exposure to the treatment was made for periods of 15 minutes on each of three successive days, and the culture was placed at a distance of 40 cm. from the lamp. The absence of a filter produced very deleterious effects upon fungus cultures.

Carboniferous Molluscs of the Donetz Basin. The first monograph of Carboniferous pelecypod molluscs found in the Donetz basin in south Russia, just published by D. M. Fedotov (Trans. Geol. Prospecting Service, U.S.S.R., fas. 103) includes detailed critical descriptions and good plates of 120 species. An interesting result of the work is that only 21 out of 120 species have been previously known from the Carboniferous of Western Europe, and a few are Russian species, while the bulk of the Donetz species proved to be either identical with, or closely related to, North American species. The species common to the Donetz basin and North America belong mainly to the Upper and Middle Carboniferous, which correspond to the strata known as Pennsylvanian in America.

Age of Meteor Crater. It is reported by Science Service that recent investigations by Prof. Eliot Blackwelder indicate that Meteor Crater, the great pit in northern Arizona that is believed to mark the impact of a flight of meteorites, is probably very much older than has generally been assumed. Past estimates have ranged from two to ten thousand years, but it is now suggested that the crater was made during the last interglacial epoch, perhaps 40,000–75,000 years ago. The evidence includes indications of a former moist climate that was of relatively long duration. At the bottom of the crater there is a deep deposit of finely pulverised quartz with many remains of diatoms and snails, interbedded with freshwater limestone, coaly material, and a single layer of volcanic ash that records an explosive eruption somewhere in the neighbourhood. The lake beds indicate a long-standing body of water, and not a succession of *playas* or seasonal ponds. At present, permanent water is not struck within 200 feet of the bottom of the pit. Other lines of evidence based on the erosive work of wind and water support the conclusions reached.

Ionisation in Electric Cables. The almost universal use of high electric pressure for the transmission of power to long distances has made it a problem of great commercial importance to increase the electric strength of the insulating wrappings round the cables so that they may be able to withstand for many years the high electric stresses to which they are continuously subjected. In a paper on "Ionization in Cable Dielectrics" read to the Institution of Electrical Engineers on March 9, P. Dunsheath discussed the rapid developments that have recently taken place in the manufacture of these dielectrics. Since its inception a few years ago, the oil-filled cable has given an excellent record of performance and this has perhaps diverted attention from the many thousands of miles of 'solid-type' cable which have been giving very satisfactory service at voltages up to 66,000 in all parts of the world. At 33,000 volts, trouble due to inherent dielectric failures is now almost unknown. The breakdown of cables is generally due to vacuous spaces called 'voids' in the dielectric. The electrical breakdown of the rarefied gas in a cable void is controlled by laws which so far are not completely established. When electrical stress is applied to gas in an enclosed space it first of all speeds up the movement of the relatively few ions present, without causing any of the usual visual or chemical effects of a discharge. When the ions are further accelerated, a stage is reached at which the ions split up neutral molecules by collision and the current through the gas rapidly increases. At this stage the effect is cumulative and a state of ionisation is attained. With our present knowledge, however, we cannot foretell the stress at which the breakdown occurs with any degree of precision. The author concludes that in high-voltage cable dielectrics the most important phenomenon is ionisation. This makes itself evident by increasing the total electric loss at a rate greater than the square of the applied voltage.

Photochemical Decomposition of Diazomethane. Kirkbride and Norrish (*J. Chem. Soc.*, Feb.) find that diazomethane, CH_2N_2, shows two regions of absorption, the first in the blue and violet, with a structure suggesting predissociation, and the second, very intense and continuous, in the ultra-violet beyond 2650 A. The primary photochemical process is an interesting one, since it appears to involve a simultaneous severance of both nitrogen atoms from the molecule. The subsequent history of the CH_2 radical, leading mainly to ethylene and propylene, but also to other by-products, can be fairly satisfactorily traced. The quantum efficiency is 4–5 for light of wave-lengths 436 and 365 mμ. In no instance could an explosion (which is readily initiated thermally) be brought about by the action of light. There is thus no evidence for a reaction chain of any appreciable length, which is somewhat surprising in view of the strongly exothermic character of the decomposition. The primary process is most probably: $CH_2N_2 + h\nu = CH_2 + N_2$. The close resemblance between the absorption spectra of azomethane and diazomethane indicates that the azo-group is present in the latter, and supports the ring formula for diazomethane. When the reaction was carried out in presence of hydrogen, methane was produced in quantity, no doubt by interaction of CH_2 groups and hydrogen, and there was a corresponding suppression of secondary reactions.

International Atomic Weights. The Table of International Atomic Weights published in the February *Journal of the American Chemical Society* contains two alterations, namely, iodine = 126·92 (in place of 126·93) and lanthanum = 138·92 (in place of 138·90). The accompanying report directs attention to the prevailing uncertainty in the factor for the conversion of values from the physical to the chemical scale. Two values are in use, namely, 1·00022 and 1·00012, the first being supported by Aston's data for the intensities of the lines O^{16} O^{17} and O^{16} O^{18} for comparison with O^{16}_2. "Since the accuracy of the mass-spectrograph is admittedly no greater than 1/10,000 and the uncertainty of the conversion factor obviously is as large, while the measurement of isotopic ratios has inherent uncertainties, the degree of precision of the determination of atomic weights from mass spectrograph data still seems inferior to that of the best chemical methods, although the striking concordance of the two methods in most cases is reassuring". The case of the isotope of hydrogen, H^2, is mentioned. The mass is found by Bainbridge to be 2·01353, assuming He = 4·00216 and H^1 = 1·00778. The atomic weight of hydrogen, with a proportion of H^2 approximately 1 in 4,000 as found from the spectrum of ordinary hydrogen, is therefore slightly higher than the value of H^1 found by Aston. The discovery of additional isotopes of tellurium and their percentages has given (with the packing fraction -5×10^{-4} and conversion factor 1·00022) an atomic weight 127·58, in much closer agreement with the chemical value (127·5) than Aston's 128·03. It may be added that the value for the atomic weight found by Baker and Bennett in 1907 was 127·60, and although 127·5 is adopted in the actual International Table, most recent chemical values are nearer 127·6 than 127·5.

Astronomical Topics

Origin of the Planetary System. A new theory of the origin of the system is proposed by Dr. R. Gunn (*J. Franklin Inst.*, June 1932). Instead of the appulse of two stars, he postulates the fission of a single star by rotational instability. He supposes that the star originally rotated in a few hours, but that after fission the strong tidal action between the components slowed it down. While the two bodies were within Roche's limit, a certain amount of disintegration took place, which is supposed to have given rise to the planets. When the star split, one side of each component had been near the centre of the star when single, and was much hotter than the other side. The reaction of the intense radiation pressure from the hotter sides made the stars separate, and the other component is supposed to have receded to a stellar distance.

The author concludes that Mars must have originally had a large satellite, to increase the time of its rotation from a few hours (less than the 7½ hours which Phobos takes to go round) to its present value. He conjectures that this large satellite escaped, and may have split up to form the asteroid family. The author was led to his theory by the consideration that the close appulse of two stars is acknowledged to be extremely rare, while the prevalence of binary systems makes one suppose that the fission of a star happens frequently. Many of the details are speculative, but it is well in a problem of such difficulty to explore every possible avenue.

Hornsby's Observations of Mercury. Dr. J. Jackson took a large part in the new reduction of the observations made by Dr. Hornsby at the Radcliffe Observatory, Oxford, during the last quarter of the eighteenth century, and the observations of Mercury have recently been discussed (*Mon. Not. Roy. Astro. Soc.*, December). The question of the phase correction is a troublesome one, as it appears that Hornsby tried to observe the true centre; solutions have been made with and without corrections. Tabular places for the sun and Mercury were computed from Newcomb's tables to compare with the observations.

The most interesting point is the motion of the perihelion of Mercury; after reducing from Newcomb's precessions to those of de Sitter, Jackson finds that the excess of the motion over the Newtonian value is 43·1″ per century, with a probable error of 1″. The value deduced from Einstein's theory is 42·9″, a satisfactory agreement.

Rather a large correction is found to Newcomb's obliquity of the ecliptic, namely, 0·53″; it is pointed out in the paper that the evidence from other planets also points to a positive correction though somewhat smaller.

There are 349 observations of Mercury in the years 1774–1798; their reduction adds very considerably to our knowledge of the elements of this planet, and their secular variations.

Annuario del Observatorio Astronomico de Madrid, 1933. This useful almanac and handbook contains particulars of the various calendars in use in the world, extensive extracts from the nautical almanacs, monthly star-maps for the latitude of Madrid, and various geographical and physical tables. The comet table needs bringing up to date; it claims to give all comets that have been observed on their return but omits (*inter alia*) Grigg-Skjellerup, Neujmin I, and Pons-Coggia-Winnecke-Forbes. Also it gives Perrine's comet as observed in 1922, though this identity is highly improbable. On page 122 the mean annual motion of Pluto is given as 1° 45′; it should be 1·45°.

Work of the Forestry Commission[*]

THE 'forest year' of the Forestry Commission ends on September 30, and that date in 1931 brought to a close the twelfth year of its work. It was inevitable that operations and a policy that are dependent upon Government grants and a present non-productive expenditure should have been subject to a close scrutiny from the May Committee on National Expenditure.

For the second decade of the Commission's work, it had been estimated that the gross cost of the whole business (purchase of land, planting, etc.) and the ancillary operations such as assistance to private forestry, education, research, etc., would amount to £11,275,000 for the decade; working receipts were estimated at £2,160,000 and the net contribution from the Exchequer was expected to be £9,115,000. The chief objectives laid down during the second decade were to plant 353,000 acres and to establish 3,000 worker's holdings. The planting programme was to be on an expanding scale, beginning with 25,000 acres in 1929 and rising to 44,000 acres in 1938, while the holdings programme was to be at the rate of 350 holdings yearly for the first five years, and 250 holdings yearly for the second five years. In order to carry out these programmes, it would be necessary to acquire each year 6,000 acres of plantable land and 2,500 acres of agricultural land.

It has been already stated in NATURE (Sept. 17, 1932, p. 427) in a note discussing a paper by Sir John Stirling-Maxwell on "Forestry and National Economy" that the sum sanctioned for the above proposals received a severe cut at the hands of the May Committee, the majority report making the following recommendation: "After weighing up all these considerations we recommend that no fresh acquisitions of land be made for the present and that no more forest worker's holdings be created, but that afforestation proceed at the rate of 20,000 acres per annum for five years on the land already acquired. This course is estimated to save £478,000 next year and £560,000 per annum in subsequent years as compared with the present policy."

In subsequent discussions with the Government, the Commissioners stated that it was desirable to maintain the main elements of forest policy, which were, briefly, the continuance of planting and of the acquisition of plantable land, and the provision of sufficient houses and holdings to work the forests economically. After due consideration, the Chancellor of the Exchequer undertook that the Government would provide annually for the next five years the sum of £450,000 which, with working receipts, would enable the Commissioners to spend rather less than £600,000 a year on forestry operations.

With this sum at their disposal, the Commissioners anticipate that they will be able to carry out the following work: (1) Maintain a planting programme of 20,000 acres a year. (2) Acquire sufficient plantable land to keep intact the reserve of land which is required for maintaining the planting programme. (3) Provide sufficient forest worker's holdings (numbering perhaps 15–20 a year) for working the forests efficiently, and also repair and maintain such holdings as are necessary for the utilisation of the non-plantable land. (4) Provide grants for planting on the same scale as during the last three years. (5) Maintain intact their research activities and make suitable provision for forestry education and other ancillary activities.

The question of forestry on private estates has been receiving the attention of the Commissioners, and the Consultative Forestry Committees of England, Scotland and Wales were consulted and a joint report presented. This report stated that private forestry is not receiving the same attention as in pre-War days, in spite of the spread of technical knowledge and State encouragement. The causes for the decline during post-War years are admitted and well known to all. In the urgent need for national economy the joint report was unable to suggest any general solution. The Commissioners appear to be of opinion that the State, in the long run, might have to relieve the private owner of his responsibility in maintaining the woodlands of Great Britain.

Apart from the question as to whether this is a correct policy, either for the State or the tax-payer, it is open to doubt whether it is even a truly economic one. In France the State forests form about a third only of the total forest area, in Sweden 20 per cent and in Germany 25 per cent. With a reduction of taxation in Great Britain, with the available technical knowledge and the advantage of the presence in the country of the Forestry Commission, it may be hoped that the land owner will find it possible to follow in the footsteps of his confrères on the Continent. The disappearance of the private forest owner was evidently not contemplated by Lord Clinton, during his tenure of the chairmanship of the Commission. In an address delivered at the annual meeting in 1928 of the Royal Scottish Arboricultural Society (see NATURE of May 5, 1928, p. 697) Lord Clinton said: "I am not at all confident that the State can properly undertake the full duties of afforestation. I think the keenness of the general public, who in theory are very keen on forestry, is likely to evaporate directly they begin to understand the great cost which will fall on them if the State shoulders the whole burden."

Soon after the close of the year under review, the chairman of the Commission, Sir John Stirling-Maxwell, resigned. Of his work for Great Britain in the cause of forestry and that of his two predecessors, Lord Lovat and Lord Clinton, it is impossible to speak too highly. Sir Roy Robinson, a technically trained forester, now assumes the chairmanship. In spite of the fears of some well qualified to speak when the Forestry Bill was passed in 1919, there is little doubt that the new Forestry Department was only able to weather the stormy times of its first twelve years owing to its fortunes being in the hands of three such able and powerful land owners as the past triumvirate of chairmen.

The Report deals in general with the work of the year ending September 1931. The net total area of land acquired in Great Britain to this date was 627,075 acres, of which 393,448 acres were classified as plantable, 58 per cent being in England and Wales and 42 per cent in Scotland. The area planted during the year was 25,630 acres, the total area planted during the twelve years being 188,985 acres, of which 177,456 acres consisted of conifers and 11,529 acres of hardwoods.

An interesting item in the Report is the valuation by the Inland Revenue authorities of the Crown properties transferred from the Office of Woods to the Forestry Commission. The chief of these were the New Forest and the Forest of Dean, the total valuation of which amounts to £1,227,495.

---

[*] Forestry Commission. Twelfth Annual Report of the Forestry Commissioners for the Year ending Sept. 30, 1931. Pp. 43. (London: H.M. Stationery Office.) 9*d*. net.

Under education and research the Report summarises the conclusions of the Irvine Committee on the training of candidates for Government forest services. The Commissioners pass no comment upon these conclusions which, it is understood, are receiving the careful consideration of the universities concerned.

Harvey and Preventive Medicine

A BRIEF account of Sir George Newman's Harveian Oration to the Royal College of Physicians of London appeared in NATURE shortly after its delivery (NATURE, Oct. 29, p. 657). The full text of the discourse has since been published in pamphlet form.*

In his discussion of the new physiology which was inaugurated by Harvey's demonstration of the mechanism of the circulation of the blood, Sir George Newman points out that in 1622, six years after Harvey's first Lumleian discourse and six before his book was published, the demonstration of the lacteals and lymphatic system by which nutriment reached the blood was made by Aselli, Pecquet and Rudbeck. In 1648 the chemistry of digestion and the blood was investigated by van Helmont. Ten years later, the corpuscles of the blood were discovered by Swammerdam and Malpighi, and in 1661 Malpighi revealed the existence of the capillaries, which had been suspected by Harvey who, in the absence of a microscope, had been unable to detect them. In 1669 the contributions to the physiology of respiration by Boyle, Hooke, Mayow and Richard Lower demonstrated the purpose and process of aeration of the blood in the lungs, its selective use of the oxygen in the air, its conveyance to the tissues by the blood, and the resulting vitality and functioning of the tissues.

In the succeeding century, the actual gases which control life—carbonic acid, nitrogen and oxygen—were separated and fresh knowledge of the nervous and digestive systems was acquired. In the middle of the nineteenth century the foundations of endocrinology were established by the work of Thomas Addison, Claude Bernard and Brown-Séquard, and since then the progress of physiology in Great Britain has been pre-eminent in quantity, quality and scope.

Sir George Newman next considers the application of these discoveries to preventive medicine. He points out that from the sixteenth century onwards, the research worker has collaborated with the private practitioner and the public medical officer in the prolongation of life and the prevention of disease. Striking examples of this statement are furnished in the eighteenth century by Lind and Sir Gilbert Blane in their defence of the health and the dietary of seamen, by William Cadogan, the pioneer in maternal and child welfare, and Sir John Pringle, who reformed the health of the Army. In recent times the labours of modern physiologists have contributed not only to the conservation of health but also to the prevention and cure of disease, as is exemplified by their work in connexion with cretinism, goitre, diabetes, anæmia, malnutrition, deficiency diseases, beri-beri, osteomalacia, scurvy and rickets.

The study of the cause and control of infective diseases is taken by Sir George Newman as another example of the Harveian method and spirit. The conveyance of infection by the circulating blood was acknowledged by Harvey's contemporaries, such as Glisson and Sydenham in the seventeenth century, and by the eighteenth century physicians who explored the circumstances and clinical features of infective diseases and observed their relation to external environment, to seasons and to meteorological conditions. Examples of such men were Huxham, who investigated typhoid, typhus, Devonshire colic, scurvy and scarlet fever; Heberden, who studied chicken-pox, measles and epidemic colds; Fothergill, who described epidemic sore throat; Haygarth, well known for his work on small-pox and typhus; Edward Jenner, who introduced vaccination, and Willan, the father of British dermatology. It is noteworthy that in spite of the absence of any exact knowledge of the causation of disease, which was not reached until the advent of bacteriology in the later half of the nineteenth century, two significant conquests were achieved by the English before the end of the eighteenth century in the control of scurvy and of small-pox.

The production of artificial immunity, which Sir George Newman rightly regards as the greatest single advance in preventive medicine, is chosen by him as yet another example of the application of the Harveian method. Although the protective qualities of the blood were known to Harvey, it is only within comparatively recent times that an explanation of this property has been found, thanks to the work of Pasteur, Lister, Metchnikoff and Sir Almroth Wright.

* "The Debt of Preventive Medicine to Harvey and the College of Physicians." (Harveian Oration, 1932: The Royal College of Physicians of London.) By Sir George Newman. Pp. 47. (The British Periodicals Ltd., 19 Cursitor Street, E.C.4.) 1s. net.

Spreading of Liquids on Solid Surfaces

IT is generally supposed that on metals as well as on water the fatty oils and fatty acids should possess a more pronounced spreading tendency than the mineral oils, yet experiments show that this is not the case. Buckley and Snyder (*J. Amer. Chem. Soc.*, Jan.) have confirmed this observation and have discovered an interesting phenomenon of rupture of thin layers of liquid on a solid surface due to the instability created by an underlying adsorbed film of low surface energy. Fatty oils and fatty acids lower the static coefficient of friction between metal surfaces more than do mineral oils of the same viscosity, and a mineral oil containing a small percentage of a fatty acid lowers the friction almost as much as a pure fatty oil. This is in agreement with a preferential adsorption of fatty acid on the metal surface, indicating that these acids lower the surface tensions of metals more than do mineral oils.

Mineral oils which spread rapidly on ordinary metal surfaces seem to have no spreading tendency on a metal surface covered with an invisible fatty acid film. When a drop of petroleum oil containing some fatty acid is placed on a polished plate, the mineral oil spreads in its normal manner, the fatty acid being preferentially adsorbed on the solid and lowering the surface tension until at a minimum thickness of liquid layer, rupture of the film occurs.

Any portion of oil in the midst of an area covered with an adsorbed film pulls itself together into a drop, whilst the oil in contact with clean metal continues to spread outward. It is supposed that fatty oils and fatty acids are prevented from spreading on metal surfaces by the great reduction in the surface energy of the metal which is brought about to some distance in advance of the spreading layer by the breaking away of an expanding ring or by the condensation of vapours.

University and Educational Intelligence

CAMBRIDGE.—Dr. N. J. T. M. Needham, of Gonville and Caius College, has been appointed Sir William Dunn reader in biochemistry in succession to Prof. J. B. S. Haldane.

V. J. Chapman, of Pembroke College, has been elected to the Frank Smart studentship in botany.

The following have been awarded Smith's prizes: E. A. Maxwell, Queens' College, for an essay entitled "The Invariants of Certain Surfaces" and R. H. Stoy, Gonville and Caius College, for an essay entitled "The Planetary Nebulæ". Rayleigh prizes have been awarded to the following for the essays indicated: W. E. Candler, Trinity College, "The Stability of the Rings of Saturn"; C. Strachan, Corpus Christi College, "Reflection by Monomolecular Films"; M. H. H. Walters, King's College, "The Effect of Stellar Encounters on the Orbits of Binary Stars".

EDINBURGH.—The Senatus has resolved that the honorary doctorate in laws be offered to the following: The Right Hon. Craigie Aitchison, Lord Advocate; Sir James Caw, formerly director of the National Galleries of Scotland; Sir Henry Dale, director of the National Institute for Medical Research; Prof. G. H. Hardy, Sadleirian professor of mathematics, Cambridge; Sir Alexander Houston, director of water examination, Metropolitan Water Board; Sir Hugh Rose, chairman of the General Board of Control for Scotland; Mr. J. C. Smith, formerly senior inspector of schools in Scotland; Mr. W. W. Tarn, author of works on the Hellenistic age.

LONDON.—The Armourers and Brasiers' Company and the Carpenters' Company have decided to make grants to the University of £2,000 and £1,000 respectively in the shape of annual payments extending over ten years; and the Ironmongers' Company has granted £500 and the Dyers' Company £105. These benefactions will be applied towards meeting the cost of the new Ceremonial Hall to be erected on the University's site in Bloomsbury.

A munificent bequest by the late Mr. Arthur L. Leon amounting to some £20,000, for the promotion and encouragement of post-graduate or advanced research work, has been accepted with great appreciation.

The Court has appointed Mr. James Stinton Jones to be consultant engineer for heating, lighting, ventilation and electrical services generally, in connexion with the new buildings in Bloomsbury.

THE Salters' Institute of Industrial Chemistry is offering several fellowships for chemists of post-graduate training, and grants-in-aid to people employed in chemical works who desire to extend their education for a career in chemical industry. Further particulars can be obtained from the Director of the Institute, Salters' Hall, St. Swithin's Lane, London, E.C.4.

THE Cecil Peace Prize of £100 is offered annually to graduates or students in any university in Great Britain or Northern Ireland for the best essay on some subject connected with the maintenance of international peace. The subject for 1933 is "Is it true that the British Empire is in itself a League of Nations ?" Further particulars can be obtained from the Secretary, Universities Bureau of the British Empire, 88a, Gower Street, London, W.C.1.

THE annual examinations for a Faraday scholarship of eighty guineas per annum, tenable for two years at the Faraday House Electrical Engineering College and one year in manufacturing works, and for a Maxwell scholarship of sixty guineas per annum, tenable for two years at the College and one year in works, will be held at Faraday House on April 4–6. Further particulars can be obtained from the Registrar, Faraday House Electrical Engineering College, 62–70, Southampton Row, London, W.C.1.

THE University of Leeds has recently issued a list of holiday courses open to all students, whether former members of the University or not, to be given during the Easter vacation, on April 19–21. Amongst the courses are one on modern psychological principles by Dr. Ll. Wynn Jones and a course of six lectures in physics, comprised of two by Prof. R. Whiddington on "Recent Advances in our Knowledge of the Electron", two by Dr. E. C. Stoner on "Recent Developments in Magnetism", one by Mr. J. Ewles on "The Photoelectric Effect" and one by Mr. F. A. Long on "Recent Low Temperature Researches". Further information can be obtained from the Registrar of the University.

THE objectives of secondary education are being much discussed in the United States as well as in Great Britain. In the October number of *School Life*, the organ of the United States Federal Office of Education, appears an article by one of the senior staff on "Schools and the Social Upheaval" in which it is argued that a primary function of education, particularly in the high schools and colleges, is to prepare the rising generation for playing their part intelligently in the solution of social, economic and civic problems. Why should the people pay in taxation two and a half billion dollars yearly to support a public school system unless it believes that an educated public is the surest safeguard of its freedom ? It is because the high schools, patterned largely on the model of the colleges evolved to serve leisured and professional classes, have failed to adapt their teaching to the task of justifying this belief that the type of education they provide is being found inadequate to present-day needs. To fulfil their task of passing on the accumulated wisdom of one generation to the next the schools must expound the beliefs of acknowledged experts in regard to social and economic affairs, and in the readjustment now due, this function and character training should, it is contended, be treated as of paramount importance.

Calendar of Nature Topics

Ice off Newfoundland

March 20.—During the winter the sea is firmly frozen in Baffin Bay and among the islands of the Arctic Archipelago, and numerous icebergs calved from the glaciers of Greenland are frozen in. Early in spring these ice masses break up and drift into Davis Strait, where they are carried rapidly south-eastwards by the Labrador Current, drifting parallel with the coast of Labrador, and entering the Atlantic off Newfoundland. Here the thin ice-floes quickly disintegrate in the warm water, but the icebergs have a longer life, drifting in the eddying currents off Newfoundland and sometimes penetrating far into the Atlantic, where they constitute a grave danger to shipping. On April 14, 1912, the s.s. *Titanic* struck a berg in long. 41° 46′ N., lat. 50° 14′ W., and sank with great loss of life. Both the amount of ice and date of arrival vary greatly from year to year, but March 20 is about an average date for the bergs to appear in quantity over the Newfoundland Banks.

The Spring Equinox

March 21.—Although in the meteorological calendar spring begins on March 1, it is often nearer the close of the month before the earth begins to awake under the influence of rising temperature and increasing power of the sun's rays. The surface of the soil first responds to the greater insolation, and an apt saying relates that on St. Patrick's Day (March 17) "the warm side of a stone turns up", signifying that about this time heat begins to flow downwards into the ground from above instead of the ground giving up heat to the air.

Spring Winds and some Biological Effects

There is no doubt that wind, especially at certain seasons, is a factor of considerable ecological importance. South-westerly winds cause a drift of the zooplankton towards the eastern shore of the Southern Bight in spring, and herring coming in through the Straits of Dover naturally veer towards their food. The spring maximum, however, of the colonial flagellate *Phæocystis* occurs off the Dutch coast. This organism is disliked by herring. On meeting it in quantity, some of the shoals turn westwards toward English waters (Savage, *J. Ecol.*, 20, 2). Easterly winds on occasion bring the plankton towards the English coast. The herring follow, unless they are repelled by an accompanying drift of *Phæocystis* in excessive amount and continue north along the Dutch coast without appearing in the Lowestoft zone.

A succession of strong spring winds in many rivers produces a very heavy mortality among the emerging subimagines of the Ephemeroptera and seriously affects oviposition by the imagines. These insects are a favourite food of various fishes, especially of trout, and excessive losses leading to a reduced stock the following year imply an effect on the faunal balance in several ways.

Elvers Arrive

For three years the young of the fresh-water eel, in the strange form of leptocephali, have been drifting across the Atlantic Ocean from their distant birthplace, and now in the post-larval elver stage, they begin to enter the rivers of the western coasts of Europe.

In the Severn the fresh-water migration of the elvers begins in March and in such quantities do they appear that they become the objective of a seasonal fishery which lasts until about the middle of May. The elvers generally ascend the river on a high tide, swimming just below the surface of the water, and they are caught by means of hand-nets of cheese-cloth supported upon a large rectangular frame. Although the elver cake referred to by Isaac Walton and other writers is no longer made, the elvers themselves, packed in buckets or barrels, are still sold as food, the dish generally being prepared by washing the elvers in salt and water and afterwards boiling them in fat.

For many years the German Fisheries Union maintained an establishment at Epney on the Severn, from which they exported 3,000,000 living elvers annually for cultivation in German lakes and rivers. In 1920 this station was taken over by the Ministry of Agriculture and Fisheries, which endeavoured to encourage in Great Britain the introduction of eel stock to rivers and lakes otherwise unprofitable.

Since the eel-migration follows the trend of the North Atlantic drift, it is to be expected that the arrival of young eels in the North Sea will be later than on the west coast of Great Britain, so that in east coast rivers the beginning of the elver migration into fresh waters generally takes place in April or more commonly in May.

Barley

Few of our crops have been studied more than barley. As the raw material for the maltster, its quality takes on great importance, which when reflected in the price, causes farmers to think more about quality than yield. A good malting barley may be worth twice as much per quarter as a coarse sample only fit for feeding. Much work has recently been undertaken to define the illusive idea of quality in scientific terms as distinct from the hand valuation of the market place. The indications are that the good-looking barleys are somewhat favoured and the less attractive rather handicapped by judgment based on external appearance.

Of the factors making for quality in barley, soil and season are the most important and are outside the farmers' control. The choice of a suitable variety of seed is a great help; indeed two varieties alone account for most of the acreage in southern and eastern England, and represent a notable achievement in the production of new strains of cereals. Next comes skilful soil management, and he may count himself fortunate who can so lay his fields that the weather can do most of the work. Finally, there is the matter of manuring, and here the art lies in exploiting the crop-producing powers of fertilisers to the full without running the risk of seriously damaging the quality. It is fortunate that a good yield is not incompatible with a high grade product. It is essential, however, that the manure shall be so measured that the crop can stand up to harvest, and this requires considerable judgment. If the seed can be laid in a good seed bed in the early days of March, the first step towards a useful crop has been taken. The rest depends on the turn of the season.

Societies and Academies

DUBLIN

Royal Dublin Society, Jan. 24. C. BOYLE and J. J. RYAN: Grass silage. Experiments were carried out on the ensiling of grass in a concrete pit silo and on the feeding of the resulting silage to dairy cows. The first cutting was started when the grass had almost arrived at the stage when it might have been cut for hay. The second cutting was taken when the aftermath was about 9 in. long. A portion of each sample was analysed chemically and the remainder weighed and put into the silo in a bag. This was weighed and analysed when recovered. The loss in dry matter in the sample bags amounted to 15·8 per cent. To this must be added the loss due to some of the material on the top and sides being unfit for feeding. This brings the loss in dry matter up to 18·5 per cent. Three feeding trials were carried out in which silage was used to replace (*a*) hay, (*b*) roots, (*c*) hay and roots. Replacement values for hay, roots, and silage, were arrived at on the basis of starch equivalents: 3·2 lb. silage = 1 lb. hay, 0·43 lb. silage = 1 lb. roots, or 2½ stones silage = ½ stone hay and 2 stones roots. M. J. GORMAN: Two forms of sampler used in estimating the number of plants per acre in botanical analyses of grasslands. An account was given of several sizes and shapes of sampler used by various grassland workers. The advantages of taking 1/100,000 acre as a unit were pointed out. This size would be convenient for most purposes; where necessary, simple multiples or fractions of it might be employed. G. C. BROCK: A method of preparing a filter for the 3130 mercury line. A photographic lantern plate is exposed and developed in pyro soda or thiocarbamide developer. Reddish-brown or blue films are produced, and afterwards stripped from the glass. Such filters show a maximum of transmission near 3000 A., as in the case of sputtered silver films, but the absorption at 4000 A. is much higher. A red-brown filter which transmits approximately the same percentage as a sputtered filter at 3130 A., has a sharper cut-off on the visible side.

PARIS

Academy of Sciences, Jan. 30 (*C.R.*, 196, 305–376). The president announced the death of the Abbé Verschaffel, *Correspondant* for the Section of Astronomy. MARCEL BRILLOUIN: Linear partial differential equations in the plane. Domains with multiple connexion. The construction of integrals for given conditions at the boundaries. JULES DRACH: The integration by quadratures of the equation of geodesic lines. J. COSTANTIN: An attempt at a theory explaining the function of the mycorrhiza of the sugar cane. RENÉ LAGRANGE: The theorem of Poncelet. F. LEJA: A property of series of analytical functions limited on a curve. A. WEINSTEIN: The points of detachment of lines of slip. PIERRE GIRARD and CH. CHUKRI: A centrifuge without an axis of perfect stability and of high angular velocity. TCHANG TE-LOU: The measurement of the supply of heat in the cycle of an internal combustion engine with the aid of the indicator diagram. ANDRÉ EGAL: A new method of realisation of thermo-electric phenomena. The construction described and illustrated allows a large number of thermo-elements to be used in series, so arranged that the whole set is not put out of action when individual elements are damaged. V. DOLEJŠEK and K. DRAB: The study of the discharge in an ionic bulb with the aid of a cinematographic apparatus. V. POSEJPAL: The atomic radius of carbon in the diamond. In a recent paper on the passage of the photonic rays by atoms some formulæ have been deduced, and these are now applied to the determination of the atomic radius of carbon in the diamond. The close agreement of the values thus obtained with those given by X-ray methods is regarded by the author as a confirmation of the formulæ. The measurements on which the formulæ are based have nothing to do directly with atomic structure. P. ROUARD: The variations of phase by reflection on very thin metallic films. The metal was deposited by cathode sputtering in the form of a wedge, so that at one end the reflection was from glass to air and at the other from glass to metal. For silver, the change of phase was at first a retardation which, after passing through a maximum, diminishes and then becomes an advance. C. JAUSSERAN: The evolution of the latent image. The density is not sufficient to characterise a developed image. Moreover, the number of variables intervening in the evolution of the latent image are so numerous that it is difficult for different observers to work under absolutely identical conditions. LÉON GION: The photolysis of aqueous solution of ammonia. In the absence of oxygen, hydrogen and nitrogen are evolved, the ratio H/N varying from 2·4 to 3. A reducing substance is formed which is not a nitrite. NÉDA MARINESCO: The preparation of colloids by ultra-sonic dispersion. The method allows the preparation of a number of metallic colloids at the ordinary temperature in any dispersing medium: the particles are spherical and can be kept for a long time in this state. G. DARZENS and ANDRÉ LÉVY: Improvement of the general method of preparation of aldehydes by the degradation of acids. A modification of Blaise's method giving nearly quantitative yields. V. HASENFRATZ: Some properties of *d*-xylonic lactone—URIAN. A 1,6-dimethyl-1, 3, 5-hexatriene. VOLMAR and BETZ: Contribution to the study of emetic derivatives of lactic acid. Description of the preparation and properties of sodium antimoniolactate, $(C_3H_4O_3)_2NaH(SbOH)$. JACQUES DE LAPPARENT: The mica schists of Léon. RAYMOND CIRY: The upper Cretaceous of the western part of the province of Burgos. OTTO PETTERSSON: A gap in the classical theory of tides. E. FICHOT: Remarks on the preceding communication. PAUL BERTRAND: The morphological value of the primary rachis of the Cladoxyleæ and the Zygopterideæ. J. RAYMOND: The formation of the perithecium in *Microsphæra quercina*. A. GUILLIERMOND and R. GAUTHERET: The microchemical characters of the oxyflavonic compounds; their localisation in the vacuoles. The reactions of oxyflavonic compounds towards various reagents have been studied in the vacuole, in extracts and with the pure product. These are tabulated and compared with results for tannin in the vacuole and in solution. Although a single reagent has a limited value, with the tests taken together, oxyflavonic compounds can be identified and distinguished from tannin without difficulty. MLLE. S. NOUEL: Technique for the study of the eye muscles in Selacians. MLLE. ANNE RAFFY: The comparison of the respiratory metabolism of the eel at some stages of its development.

Cape Town

Royal Society of South Africa, Oct. 19. S. M. Naudé and J. E. C. Coventry: Intensity of cosmic radiation in South Africa. The results obtained in July, 1932, at eight different altitudes ranging from sea level (Cape Town) to 9,200 ft. (Mont-aux-Sources) show the usual increase of the intensity with the altitude, that is, with the fall of the barometric pressure. The graph of intensity/barometric pressure, for South Africa (mean latitude 28°S) lies between those representing Compton's determinations in New Zealand (42°S) and at a point 4°S, thus verifying the dependence of the intensity on the latitude. H. A. Shapiro: The kitchen-middens at Gordon's Bay. The bored-stone would seem to be a late addition to the kitchen-midden or 'strandloper' culture. Pottery would seem to be late, and is not present in all the middens. Previous to the appearance of these two elements the culture produced only formless stone instruments, shaped by their use, and without intention. The middens seem to overlie natural dunes. Two skeletons (the skulls having been removed some years before) were discovered. From Dr. D. Slome's description, these would fall within the San race.

Geneva

Society of Physics and Natural History, Dec. 15. H. Lagotala: The geology of the Comba region (north of Mindouli, French Equatorial Africa). The author continues the study of this region, formed by oolitic limestones and much folded siliceous limestones. M. Gysin: Petrographical researches in the Haut-Katanga. (1) Geological outline of the southern part of Haut-Katanga. The author gives a geological sketch of this region, which is 300 km. by 60 km. in extent. A series of geological maps (scale 1 in 20,000) have been drawn. R. Wavre: Polydromy of potentials and topology. M. Junquera: The combined influence of *p*H and glucose on the permeability of yeast to methylene blue. The addition of glucose in acid medium increases the staining effect of methylene blue on yeasts; the increase of coloration due to the glucose changes specifically in alkaline medium.

Rome

Royal National Academy of the Lincei, Nov. 6. L. Palazzo: Materials for the reconstruction of the magnetic maps of Italy: (4) Piedmont. U. Cisotti: Finite rigid displacements. G. Quagliariello: Presence in the bile of an enzyme which dehydrogenates stearic acid. Previous results have indicated that either the pancreatic juice or the bile contains a dehydrogenase capable of acting on higher fatty acids. Experiments with stearic acid show that such an enzyme occurs in the bile. R. Caccioppoli: A principle of inversion for functional correspondences and its applications to equations with partial derivatives (1). L. Chamard: (α) Points as described by Georges Durand. S. Cherubino: Further considerations on the classification of hyper-elliptic surfaces from the real point of view. B. Finzi: Vectorial tensors and their derivation. D. D. Kosambi: Differential geometry and calculus of variations. M. Kourensky: Integration of the equations to partial derivatives of the second order with two functions of two independent variables. (1) General case. G. Pfeiffer: (1) Simplification of L. Bianchi's investigations, generalising the character (S. Lie) that the parameters are essential. (2) Linearly independent solutions of the linear equations to the partial derivatives of the second order with two independent variables. A. Rosenblatt: The question of unicity for the solutions of equations to partial derivatives. B. Segre: Claim for priority. M. Gleijeses: Theory of 'wake' in perfect liquids; case of the circular cylinder. N. Carrara: Corollary to the theorem of the derivation of definite functions from integrals; application to the experimental methods of measuring physical magnitudes. E. Segrè: Quadrupole lines in X-ray spectra (2). Various theoretical considerations are discussed and an interpretation is given of the new experimental material which has been acquired during the past year and supports the attribution of the forbidden lines of X-rays to the irradiation of the quadrupole. P. Pratesi: Thiocyano- and thio-pyrroles, and pyrrole disulphides. By direct thiocyanation with an alkali thiocyanate and bromine, 2:4-dimethyl-3-carbethoxy-5-thiocyanopyrrole and 2:4-dimethyl-5-carbethoxy-3-thiocyanopyrrole have been obtained from the corresponding dimethylcarbethoxypyrroles. They are highly stable, crystalline compounds and may be used for the identification of the pyrrole derivatives. When reduced with zinc and acetic acid, they give the thiopyrroles in good yields. O. Renz: The tectonic position of the shaly clays between the mesozoic chain of Gubbio and the Tiber valley. M. Mitolo: Avitaminosis and intoxication. (1) Experimental polyneuritis and chemical intoxication from metals and metalloids. The nutritional deficiency of pigeons affected by experimental polyneuritis is enhanced by ingestion of mixtures of salts of various metals and metalloids in doses insufficient to produce poisoning in normal animals. Moreover, the harmful effect of the salts is also increased.

Vienna

Academy of Sciences, Nov. 17. Georg Koller and Gerhard Pfeiffer: (1) The constitution of pinastric acid. This acid, occuring, together with usnic and vulpic acids, in *Cetraria pinastri* and *C. juniperina*, has the empirical formula $C_{20}H_{16}O_6$ and yields anisic and benzoic acids on oxidation. On the basis of these and other reactions, two alternative structural formulæ are suggested for pinastric acid. (2) Glabratic acid. This acid, a constituent of *Parmelia glabra*, is identical with lecanoric acid. Eduard Haschek and Max Haitinger: A simple method of determining colour. By means of a method based on the Young-Helmholtz theory, photometric measurements under three filters give data which allow of the calculation of saturation and brightness. Leopold Kölbl: The northern edge of the Tauernfenster between Mittersill and Kaprum. Franz Grienl, Oswald Kofler and Maria Radda: Experiments on the relations between turbulence-friction and constitution of liquids. Max Pestemer and Oscar Platten: The conductivity of binary or ternary, partially miscible liquid mixtures with one component which is at least slightly electrolytic.

Nov. 24. Gustav Kürti: Magneto-rotation in coloured glass and rock salt. With these substances, no measurable alteration in the electromagnetic rotation of the plane of polarisation occurs as the result of intense Becquerel radiation. Herbert Schober: The spectra of rhenium: (3) the arc spectrum with copper electrodes in the visible region between 5400 and 4000 A. Alfred Pongratz and Alois Zincke: Investigations on perylene and its derivatives (39).

Forthcoming Events

Saturday, March 18

Royal Anthropological Institute, at 2.15.—(at St. John's College, Cambridge).—Dr. L. S. B. Leakey: *"Discoveries of Human Remains at Kanam and Kanjera (Kenya)"*.

Royal Institution, at 3.—Developments in Cinematography: A Display of Films, (1) Instructional Films.

Monday, March 20

University of London, at 4.30.—(at the Royal Veterinary College).—Sir Arnold Theiler: "The Pathology of Osteodystrophic Diseases of Domesticated Animals and their Causes" (succeeding lectures on March 21 and 23).

Royal Geographical Society, at 8.30.—M. Jean Delacour: "Some Contrasts in the Civilizations of Indo-China".

Friday, March 24

Royal Institution, at 9.—Lord Ashfield: "London Passenger Transport".

Saturday, March 25

Royal Institution, at 3.—Developments in Cinematography: A Display of Films, (2) Colour Films.

Chemical Disarmament

BY the British Draft Convention submitted to the Disarmament Conference at Geneva on March 16 by Mr. MacDonald, chemical, incendiary and bacterial warfare is prohibited on the lines already accepted by the Conference. It is therefore of particular interest now to consider the replies of the Pilotti Special Committee to a questionnaire on chemical, incendiary and bacterial weapons submitted to this Committee by the Bureau of the Disarmament Conference. The Special Committee's report* is an important document, and its study should assist to engender a sane and healthy opinion on an essential aspect of disarmament.

The most important feature of the Committee's report as a whole is the emphasis it places on the intricate relations of chemical warfare and chemical industry. It points out, for example, in one of its major conclusions, that the prohibition of the manufacture, import and possession of apparatus and substances exclusively used for chemical warfare, while possible, would only be of limited value. The manufacture of those substances which were of any importance in war could be improvised by any State possessing a chemical industry. "Any such prohibition imposed upon a State would either be ineffective in practice, in view of the stocks held in industrial establishments, or it would inflict irreparable damage on the chemical industry."

It will be recalled that, in "The Riddle of the Rhine", Major Lefebure asserted that grave disparity in the strength of the chemical industry of different countries constitutes a definite menace to world peace, and the Pilotti Committee may at first sight appear to be endorsing Major Lefebure's views and those shared by many others having expert knowledge of chemical industry. Actually, however, the views thus presented are much more negative and pessimistic than those of Major Lefebure, and we question whether they would find widespread support in professional circles.

No sensible man denies the intimate connexion of chemical industry and chemical warfare or the folly of attempting under the guise of chemical disarmament to impose a rigid and bureaucratic control on chemical industry. Equally, however, no sensible man would forget, as the Pilotti Committee appears to have done, that the main concern of chemical industry is with peaceful industry, that unlike the armaments industry, it has no interests vested in war, and that, as Major Lefebure insists, the existence of large stocks of war chemicals used in industry has no meaning for war unless the appropriate containers or chemical weapons have been designed and put into stock in corresponding quantities.

---

* Chemical, Incendiary and Bacterial Weapons Special Committee. Conf. D. 152. League of Nations Publications Department. (9) Disarmament, 9, 65. (London: G. Allen and Unwin, Ltd., 1932.)

It is this preoccupation of chemical industry with peacetime activities, on which its expansion and development mainly depend, that constitutes not merely an obstacle to thorough-going chemical disarmament but indeed the best hope of a satisfactory solution. If due precautions are taken against the growth in this field of interests directly concerned with the encouragement or expansion of chemical warfare, chemical industry should continue to exert, not an influence unfavourable to disarmament, but a safeguard to the disarmed State in the readiness with which in emergency its resources could be improved for its defence.

The Pilotti Committee asserts, and rightly, that interference with the legitimate stocks of material held by chemical industry is unjustifiable and dangerous. It fails to observe, however, that, apart from the question of containers and apparatus raised by Major Lefebure, the magnitude of such stocks is limited by the internal demands of industry itself. No industry accumulates stocks of any material under normal conditions in excess of those required to meet its normal manufacturing and sales demands, and the prohibition of the holding of stocks of war chemicals by State departments, if observed in good faith, should effectively prevent the growth of a direct interest in chemical warfare as a regular outlet for the products of chemical industry.

The close relation of chemical warfare to chemical industry makes this question of control of stocks the critical one and almost the only point at which definite control can be considered. There is, for example, in some quarters much excited talk about prohibiting chemical or other research which might facilitate preparation for or developments in chemical warfare. The Pilotti Committee in its report administers an effective cold douche to such talk when it points out the danger of any such prohibition preventing also chemical and pharmacological research, which forms an essential element in the development of insecticides, fumigants and fungicides, seed disinfectants, antiseptics, medicinals and drugs. Man cannot afford to relax his efforts to overcome the forces of Nature and to combat the scourge of disease.

Nor is research on protective apparatus or appliances for the use of poisonous substances any easier to single out for restriction or repression. Industry itself is continuously demanding the improvement and much more widespread use of protective devices like the gas mask, and impediments to research in this field would be purchased dearly by human suffering in industry. Similarly, the apparatus used for producing fungicidal or insecticidal sprays when combating diseases of plants can also be used for creating clouds of poisonous substances in warfare. Certain types of fire-extinguisher can readily be converted into flame-projectors which are equally effective for military purposes or for destroying locusts.

The Committee emphasises, therefore, the limited value of prohibition of the preparation, importation, exportation and possession of substances exclusively suitable for chemical warfare, in view of the impracticability of prohibiting research on either poisonous substances or protective or offensive apparatus which are of industrial significance. It makes, however, a most significant omission, for the report contains no reference whatever to the *ad hoc* establishments maintained by governments for research on chemical warfare. This is the point on which the advocates of chemical disarmament are likely to seize. If research in this field is of such industrial importance as is claimed for it, the work is more fittingly and efficiently carried on in industry than in a government establishment, where attention is at least liable to be concentrated on the military rather than the industrial aspects. If we are told that such work cannot be carried out in industry, we are inclined to suspect its real value to humanity and to maintain that a general agreement to discontinue all State research on chemical warfare, defensive or offensive, would provide a highly desirable obstacle to the rapid improvisement of chemical warfare in the event of hostilities.

The silence of the Committee on this important point is disappointing but its importance can be overstressed. Without entering on a discussion as to whether or not chemical warfare is the most humane means of conducting warfare, if warfare we must have, the value of chemical disarmament by itself is insignificant. The Committee renders a real service in its consistent emphasis upon the relation of chemical disarmament to general disarmament. It points out, for example, that by far the greater part of projectiles charged with poisonous substances in the War were projectiles of ordinary types; that it knows of no means of projection exclusively suitable for chemical warfare; ordinary guns may fire poisonous shells and ordinary aeroplanes transport receptacles filled with poisonous substances; and that these similarities destroy the practical value of any prohibition of training of armed forces in the use of chemical weapons. The troops are inevitably trained for chemical warfare in the normal course of their training.

The attempt to treat chemical warfare as a side issue is not only futile and misleading but may even have disastrous results. It can merely engender a false sense of security, and the major value of the Pilotti Committee's report lies in the convincing evidence it affords that chemical disarmament is only possible as part and parcel of a general and genuine disarmament scheme in every sphere. Given the good faith and genuine will to disarmament which is implicit in any such plan, chemical disarmament appears to present no real obstacle to progress, and could be effected without endangering security. While it is true, as the Committee observes, that the existence of an important chemical industry in any country permits the rapid improvisation and organisation of chemical warfare even when no special preparation has been made in peace time, the installation or adaptation and starting up of the manufacture of the necessary toxic materials on a large scale require a certain time, and this lag affords the check that is the essence of real disarmament.

The ease with which chemical industry can divert its energies to the production of munitions of war, whether in the sense of high explosives or chemical weapons, should not be allowed to obscure the fact that a definite time lag does in fact exist. The fundamental question is whether our national or international system is to be organised for peace or for war. If the answer is peace, the mere existence of widespread chemical industry preoccupied with the legitimate interests of commerce and industry, tempted by no outlets for its products for offensive purposes, offers a safeguard rather than a menace to the world, so long as that peace is organised and kept. The distribution of natural resources and chemical industry in the world is such as to ensure that any transgressor State must be in a position of technical inferiority to collective reprisals from the rest of the world.

The Pilotti Committee has prepared a report which, while of unequal merit, contrives to make certain essential points beyond question—chemical disarmament is not a matter to be discussed apart from the general question of disarmament, and no restrictions can be devised which, if mankind is so foolish as to perpetuate the present armed peace, can be effective to prevent the liberation of the destructive and terrifying forces of chemical warfare.

Innermost Asia

On Ancient Central-Asian Tracks: Brief Narrative of Three Expeditions in Innermost Asia and North-Western China. By Sir Aurel Stein. Pp. xxiv + 342 + 102 plates. (London: Macmillan and Co., Ltd., 1933.) 31*s.* 6*d.* net.

IT is just on a third of a century ago that Sir Aurel Stein began his exploration of 'innermost Asia'. By 1916 he had covered, on horse and foot, a distance in the aggregate of 25,000 miles in the course of three expeditions to Chinese Turkistan—the first in 1900–1, the second in 1906–8 and the third in 1913–16. It will be fresh in the memory of all that a fourth journey begun in 1930 proved abortive owing to the difficult attitude of Chinese authority.

The mere extent of the ground covered in these three expeditions, great as it may seem with such primitive means of transport—camel, pony and man—as alone were available, is but an imperfect gauge of Sir Aurel's achievement. The greatest powers of endurance and tenacity of purpose were needed to carry it through, in face of the trying climatic and geographical conditions. The discovery and excavation of these long-forgotten desert sites could be carried on only in winter. In part this was due to the heat of the summers, in part owing to the difficulty of transporting water in the desert in any form but that of blocks of ice. It is not surprising that the workmen were unable to endure more than a comparatively short period of continuous labour when exposed to the icy, sand-laden winds in a temperature that hovered normally somewhere about zero. It was in such conditions that Sir Aurel Stein secured a mass of geographical and topographical data and of archæological material which has enabled him to revive, like a palimpsest, a long and important forgotten chapter, or rather series of chapters, in the history of civilisations.

The results of Sir Aurel Stein's journeys in

Chinese Turkistan and the adjacent areas have already been made known to the scientific world in a series of carefully documented reports and in two volumes containing his personal narrative. Of the latter, one is out of print; of the former, those which are not out of print, if only on account of their cost, are beyond the reach of the ordinary individual. In the volume now before us, Sir Aurel has compiled a personal narrative which forms a composite picture. In this, ignoring chronological order, he conducts his readers over the whole of the ground traversed in geographical sequence, and describes in sufficient detail each of the sites excavated as well as the principal results. He has in this manner made the complete circuit of Chinese Turkistan, with a detour into China proper, starting from Kashmir and returning along the foot of the T'ien Shan on the northern boundary to cross the Pamirs. The wider public to whom this personal narrative will be accessible owes the author a debt of gratitude that, amid the labours and disappointments of the last few years, he should have had the courage and energy to prepare and see through the press a work which will admit them to an intimate view of his great achievement.

The scientific results—topographical, geographical and archæological—of the three journeys were remarkable. They are too extensive for even bare enumeration here; but it may not be out of place to note one or two of the more outstanding. Much unsurveyed country was mapped—in the Nan-shan ranges alone some 24,000 miles were covered by plane-table—and much unexplored country was crossed, this more particularly on the northern boundary, a journey which was illuminating in the light it threw on the activities of the Mongols. No less interesting were the historico-topographical results, especially in the ancient Lou-Lan, by which were verified the records of early Chinese travellers and of the Imperial annals. They fully bear out the evidence which had made this desert the great artery joining China to the West, and showed that it had been held in turn by garrisons of Chinese, Indo-Scythians, and Tibetans, as well as the later Huns, Turks and the great Manchu emperors of China in the eighteenth century.

One of the problems upon which Sir Aurel's investigation has an important bearing is that of the causes which have led to the destruction of these sand-buried cities and the disappearance of the oases of the Tarim basin in which they stood. He holds the view that the evidence does not point to any continuous and progressive desiccation due to climatic variation, such as has been postulated; climatic conditions evidently have remained unchanged for centuries. It would appear that fertility depended upon irrigation, which became disorganised in unsettled political conditions and thus allowed desert conditions to prevail once more. On the other hand, he accepts the hypothesis that shrinkage of the glacier-fed rivers, which now makes any revival of fertility impossible, may be due to the gradual disappearance of the 'fossil' ice left from glaciations of the Ice Age.

In archæology, the thrills of discovery abound. From the first find of Buddhist art in Khotan—the first indication of the all-pervading influence of Western art, Iranian, Greek, Græco-Buddhist, in the Tarim basin and beyond—and the clay-sealed wooden documents at Niya, the interest rises until it culminates in the revelations of the store-chamber in a cave-temple in the oasis of Tun-Huang, in which were early Chinese, Buddhist and other writings and Buddhist paintings on silk of the T'ang period. Of these a rich store ultimately found a resting place in the British Museum. They have provided a mine for the delving of scholars over a long period of years and are still not exhausted. The wooden official documents, of which some of the sealings are pure Greek in subject, have been found to contain the earliest known examples of the Indian Karoshthi script, dating from the early centuries of our era; while among the documents from Tun-Huang are languages previously unknown, one of them, Tokharian, an Aryan language, which exhibits the anomalous feature that its affinities are with the western group of those languages, rather than with the eastern.

It is clear from internal evidence that Sir Aurel's expeditions were brought to a successful end only by the most careful organisation. This serves to emphasise a fact which is inevitably borne upon the reader of his book. The great Chinese expedition to Farghana of an army of 60,000 men, of whom 30,000 were successfully brought across the desert, under the Han dynasty, the maintenance of a system of desert forts, and the building of a protective wall, of which Sir Aurel traced the course for four hundred miles from the Su-lo-ho basin to the Etsin-gol, all bear witness to the organising ability and powers of recuperation of the Chinese. It seems to afford some justification for those of them who now regard the present situation, which for any other people might be looked upon as crushing, as no more than a phase which will pass.

It is no exaggeration to say that Sir Aurel Stein's record will rank with the great books of travel. In point of style it contains what is probably his best work. A restrained but vivid narrative sustains its interest from the first page to the last. No little praise is due to his publishers, who evidently have spared no pains to give his story a worthy setting. Few if any books of travel and archæological exploration have been more liberally and adequately illustrated, while the reproductions in colour of Buddhist paintings deserve the highest commendation.

Old Wine and New Bottles

A Text-Book of Physical Chemistry. By Dr. J. Newton Friend. (Griffin's Scientific Text-Books.) Vol. 1: *General Properties of Elements and Compounds.* Pp. xii+501. (London: Charles Griffin and Co., Ltd., 1932.) 24*s.* net.

"WENT to the Royal Institution last night in hopes of hearing Faraday lecture, but the lecture was given by Mr. Pereira upon crystals, a subject of which he appeared to be master, to judge by his facility and fluency. . . . Met Dr. Buckland and talked to him for an hour, and he introduced me to Mr. Wheatstone, the inventor of the electric telegraph. . . . There is a cheerfulness, an activity, an appearance of satisfaction in the conversation and demeanour of scientific men that conveys a lively notion of the *pleasure* they derive from their pursuits."

Thus far the author of the Greville memoirs under date March 17, 1838.

Nearly a century has passed, and a modern lecture on crystals, still most appropriately given at the lecture table of the Institution, would reveal secrets of atomic structure far transcending the scope of the discourse of the learned Dr. Jonathan Pereira; nevertheless, our men of science bear very lightly the vast weight of a century's accumulated knowledge, and cheerfulness and activity still dominate the conversations of the Royal Institution.

They who work on border-line subjects may be expected to feel most heavily the pressure of this accumulation. The physical chemist of to-day has to be both physicist and mathematician, at home with the developments of quantum theory, and competent to handle the theorems of statistical mechanics. Withal, there is scarcely anything of the older knowledge which he can afford to shed, and it will be an ill day for him when he loses the outlook peculiar to the chemist. The phase rule and Le Chatelier's theorem are weapons as potent as ever they were; and the skilled chemist must have at command much detailed knowledge of thermal and optical quantities, of surface and viscous forces, of equations of state and kinetic theory; in short, he must be well acquainted with the topics discussed in the first volume of Dr. Newton Friend's treatise, and with much besides.

In a brief review, it is impossible to do more than to summarise the headings of the twenty-two chapters which the book comprises—elementary kinetic theory, vapour pressure, critical phenomena and gas liquefaction, change of state, volume relations, the crystalline state, viscosity, surface tension, optical properties, solubility, diffusion, osmosis, adsorption and the colloidal state are chief among the properties dealt with in this first volume.

It is significant that, with such a list of subjects under review, the general index to the volume contains no entry under the heading 'quantum', nor are the names Debye, Einstein and Bragg listed. It must be said emphatically that this remark is not made by way of criticism—it serves merely to show that, in this volume at least, the author is concerned to deal with that mass of basic older knowledge with which every chemist may be expected to be conversant.

The treatment of these topics is, within the limits indicated, fairly full, though on the whole elementary in outlook. It would surely save time and trouble if, for example, the 'equal-root' method of deducing the critical constants in terms of those of the equation of state were abandoned for the more general method which involves writing down the analytical condition for a point of inflexion with a horizontal tangent. Not every equation of state is a cubic equation.

Two minor points may be noted. In the diagram on p. 99 representing the law of rectilinear diameters, the diameter is surely sloping the wrong way (compare van't Hoff, "Vorlesungen", vol. 3, p. 19). Again (p. 262), we read that the general relation connecting surface tension and temperature is

$$\sigma = \sigma_0 \ (1 - \alpha t + \beta t^2),$$

which it certainly is not.

The remaining volumes of Dr. Friend's treatise will be awaited with interest.

ALLAN FERGUSON.

Cantor: the Mathematician of the Infinite

Georg Cantor Gesammelte Abhandlungen: Mathematischen und philosophischen Inhalts mit erläuternden Anmerkungen sowie mit Ergänzungen aus dem Briefwechsel Cantor-Dedekind. Herausgegeben von Ernst Zermelo. Nebst einem Lebenslauf Cantors von Adolf Fraenkel. Pp. vii + 486. (Berlin: Julius Springer, 1932.) 48 gold marks.

"INFINITY," wrote the schoolboy, "is the place where things happen that don't." Similar opinions concerning the paradoxes which arise from the consideration of the infinite and the infinitesimal have been expressed for more than two thousand years. About 450 B.C., Zeno put forward four such paradoxes, of which the best known is "Achilles and the Tortoise". In the seventeenth and eighteenth centuries infinity and the infinitesimal were used very recklessly, and when at last mathematicians sought to return to the Greek standard of accuracy, they were unanimous in rejecting the use of infinity as something completed. But what all had rejected Cantor chose as his foundation stone.

Georg Cantor was born in 1845 at St. Petersburg, the son of a Dane. Georg soon showed an intense interest in mathematics, but was compelled to study engineering. His love for mathematics continued, and his father at last agreed that he should devote himself to it. In 1863 he went to Berlin, where Kummer, Weierstrass and Kronecker were professors. He obtained his Ph.D. degree in 1867, and one of his theses was that "in mathematics it is more important to state a question properly than to solve it". Actually the great importance of his later work lay more in the ideas and notation than in the actual results. In 1869 he became *privatdozent* at Halle, afterwards obtaining a professorship. In 1872 he produced his well-known theory of irrational numbers, published about the same time as the similar theories of Méray, Weierstrass and Dedekind, who share the credit of clearing up difficulties that had lasted from the time of the Greeks.

Cantor will be for ever famous as the creator of the theory of aggregates. This met with much opposition, especially from Kronecker, to whom Cantor's 'actual infinity' seemed a gratuitous return to the old errors which had corrupted mathematics for so long. Cantor was deeply distressed by this opposition, and in 1884 he suffered a mental breakdown, which recurred from time to time up to his death in 1918.

Some of Cantor's ideas can be understood by those with no knowledge of mathematics. In what follows some modifications due to Hobson have been incorporated. Consider the positive integers, 1, 2, 3 . . . This is an example of an *infinite aggregate,* which has the special property of being *simply ordered*; that is, given any two elements, we can tell which comes before the other. It has the further property of having a first element, and every other aggregate formed by taking part of the whole has the same property. Such aggregates are called *well-ordered.* A second simply ordered infinite aggregate that is also well-ordered is given by the even positive integers, 2, 4, 6 . . . These two aggregates are said to be *equivalent,* that is, there is a one-to-one correspondence between the elements of each, so the whole is equivalent to its part! In this case the equivalence is of a special kind known as *similarity,* that is, the corresponding elements occur in the same order. All simply ordered aggregates which are similar to one another are said to have the same *order-type.* The order-type of our first example, and so also of our second, is denoted by ω. The order-type of a well-ordered aggregate is called its *ordinal number,* so ω is a *transfinite* ordinal number.

A third aggregate, of a different kind, is formed by the positive rational numbers, for example, two-sevenths, three-fifths. If the elements are arranged in order of magnitude the aggregate is simply ordered, as we can tell which of two numbers is the smaller, but not well-ordered, as there is no first term, for given any rational number we can find a smaller one; the aggregate is *everywhere dense,* that is, given any two rational numbers, we can find others lying between them. This aggregate is not similar to the first or second, but let us re-arrange it as follows:

$$\tfrac{1}{1}\ ;\ \tfrac{1}{2}\ ,\ \tfrac{2}{1}\ ;\ \tfrac{1}{3}\ ,\ \tfrac{3}{1}\ ;\ \tfrac{1}{4}\ ,\ \tfrac{2}{3}\ ,\ \tfrac{3}{2}\ ,\ \tfrac{4}{1}\ ;\ \ldots$$

so that the sum of the numerator and denominator is 2, 3, 4 . . . in the first, second, third . . . group; each group contains a finite number of elements, arranged in order of magnitude. This fourth aggregate is simply ordered and well-ordered; it is also similar to our first and second. The third is equivalent to the others, but not similar to them.

Aggregates which are equivalent are said to have the same *power* or *cardinal number.* Aggregates equivalent to our first are called *enumerable,* and their cardinal number is denoted by *a* or by *Alef-zero*. Cantor's first great discovery was that the aggregate of all real algebraic numbers, that is, the real roots of algebraic equations with integral coefficients, is enumerable, but the aggregate of *all* real numbers (including non-algebraic irrationals such as π and e) is not. The cardinal number of the latter aggregate is called the *power of the continuum*, and is denoted by c. It corresponds to the infinite set of points in either a finite or infinite straight line, and, strange to say, also to those in a square or cube. The attempt to find cardinal numbers greater than c leads to the general theory of transfinite numbers.

Burali-Forti's discovery in 1897 (anticipated by Cantor in 1895) that the theory of transfinite ordinal numbers led to a paradox, started a controversy that is not yet settled. Some say, with Poincaré, "There is no actual infinity. The Cantorians have forgotten this and so have fallen into contradiction." Others, such as Zermelo, believe that Cantor's work, although defective as it stands, can be made sound by the explicit postulation of a suitable set of axioms, but no such set has yet been universally accepted. Many consider that some of Cantor's definitions, which do not tell us how to construct the entities in question, contain latent self-contradictions. Whatever view is taken on these questions, Cantor's more elementary ideas have become indispensable in the exact formulation of results in analysis and geometry.

H. T. H. PIAGGIO.

Short Reviews

Physical Chemistry. By Prof. Dr. John Eggert. Translated by Dr. S. J. Gregg. A translation of the third edition of "Lehrbuch der physikalischen Chemie" revised in collaboration with Prof. Dr. Lothar Hock. Pp. xi + 632. (London: Constable and Co., Ltd., 1932.) 24*s*. net.

THE third edition of Prof. Eggert's "Physical Chemistry" has been translated by Dr. Gregg, of King's College, London. The book is divided into three parts. The first part on "Atomics and Energetics" includes sections on classical chemical theory, thermodynamics, kinetic theory and quantum theory, all treated very briefly in about eighty pages. The second part, on "The Nature of Matter", occupying about 230 pages, is divided into three main sections, atoms, molecules and states of aggregation. The third part, on "Chemical Reactions" which occupies the remaining half of the book, has five main sections, on chemical equilibrium, thermochemistry, electrochemistry, chemical kinetics and photochemistry.

In general, Prof. Eggert's book deals only briefly with the topics which were taught under the name of physical chemistry during the pre-War period; but it describes much more fully the themes which have been developed during the subsequent years. There are thus ample references to electrons, isotopes, atomic and molecular spectra, crystal lattices, strong electrolytes, activity coefficients, active molecules and chain reactions, whilst the properties of dilute aqueous solutions and the theory of electrolytic dissociation no longer occupy the predominant position which was given to them in earlier textbooks. This change of emphasis corresponds with the liberation of physical chemistry from the limitations of the preceding decades; and the wide outlook of the present volume is an indication of the debt which chemists owe to an inrush of sound physics into their science.

The English version of Prof. Eggert's book may indeed be welcomed because it presents a readable and attractive account of the 'chemical physics' by which the rudimentary 'physical chemistry' of the preceding generation has now been so largely replaced.

A Textbook of Pharmacognosy. By J. W. Cooper and T. C. Denston; with Illustrations and Drawing Notes by M. Riley. Pp. x + 298. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 10*s*. 6*d*. net.

ALTHOUGH the title of this book is a little misleading—it should surely have been "A Textbook of Practical Pharmacognosy", according to the very principle laid down in the authors' preface—its use will probably extend well beyond the circle of students for whom it is primarily intended. In that sense, it may well act as a substitute for larger works of reference on the shelves of those who have only occasionally to tackle the description and identification of natural drugs.

For these, however, the purely haphazard arrangement of plant families, varying in the different sections (occasionally even two representatives of one family occur in different places in the same section), is a disadvantage only partly set off by a good index. Surely some standard arrangement, such as that of Bentham and Hooker, could have been used throughout. The drawings, on the other hand, should be of good service to users of the book, though a few that have been omitted might well be included (for example, *Chiretta*, for comparison with *Lobelia*).

The tests described are comprehensive and well explained, even if the advertisement of a particular brand of malt extract (p. 4) seems a little gratuitous; there are plenty of other diastatic extracts on the market. Print and binding are of the quality that a reference book needs—simple, clear and durable.

A. L. B.

Elementary Trigonometry. By Dr. John Prescott and H. V. Lowry. Pp. xi+444. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1932.) 5*s.*

IN this volume the authors "have tried to recapture the spirit of some of the writers of a few generations ago who looked on Trigonometry as a branch of applied rather than of pure mathematics". The course mapped out is therefore different in many ways from that found in most other textbooks. Great stress is laid on "the kind of calculations and manipulations of trigonometric expressions that occur in the applications of the subject". Theory is not neglected, but it only enters where it is necessary to establish practical formulæ. The scope is fairly wide and includes an excellent section on mensuration and solid geometry. A welcome feature is the introduction of radian measure at the beginning.

Cartesian geometry is freely used in establishing many of the standard theorems, and special attention is given to graphs and their uses. A novel feature is the addition of an appendix in which is discussed a geometrical method of calculating π to any degree of accuracy without using trigonometry.

Whilst many teachers may not agree with the general treatment, yet they will find much to stimulate interest together with a good selection of exercises, many of which are of an unusual type.

General Science. By F. Fairbrother and E. Nightingale. Part 1. Pp. viii+136. (London: G. Bell and Sons, Ltd., 1932.) 2*s.* 3*d.*

GENERAL agreement is now reached upon the importance of giving all normal pupils in all schools some instruction in the nature of the environment in which their lives must be spent. For this purpose courses have to be planned which shall give the elements of physics, chemistry, biology, geology and astronomy. Until much more experience has been gained there is likely to be great diversity in such proposed courses.

The physical and chemical parts proposed by Fairbrother and Nightingale begin with experiments on the Bunsen burner, combustion, distillation and crystallisation. Then follows the measurement of length, area, volume and density and experiments on buoyancy and flotation. Thermal expansion, thermometry, pressure in liquids and in the atmosphere and the chemistry of the air complete the first part of the course, which is well illustrated by clear diagrams and everyday applications.

At present the value of any course in general science can be assessed only by the user—so much depends upon the teacher—and it is to be hoped that bold experimentation in the choice and treatment of topics will not be cramped by external examination systems and will lead to the production of many books of a standard similar to the present one.

An Introduction to Organic Chemistry. By Prof. Ira D. Garard. Pp. ix+296. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 16*s.* 6*d.* net.

THIS is an expensive introduction to organic chemistry, which does not offer any particularly novel features. The type of treatment is indicated by the first few chapter headings, which run as follows: introduction, methane and related compounds, alcohols and ethers, halogen derivatives of the paraffins, unsaturated hydrocarbons, aldehydes and ketones. The descriptive work is well done, and the accompanying graphic formulæ are set out very clearly. Some of the space devoted to the accounts of individual substances might have been used to greater advantage in a fuller exposition of such general matters as the fundamental principles of stereochemistry and the nature of cyclic compounds. Thus, the constitutions of quinoline, isoquinoline, and more complex heterocyclic substances are presented without explanation before benzene has been discussed; and even when benzene is reached, its constitution receives scant attention. The final chapter contains laboratory directions for twenty-eight simple experiments in organic chemistry. The book contains fifteen diagrams, mostly of apparatus.

Foundations and Methods of Chemical Analysis by the Emission Spectrum. Being the authorised translation of "Die chemische Emissionsspektralanalyse" by Dr. Walther Gerlach and Dr. Eugen Schweitzer. Pp. 123. (London: Adam Hilger, Ltd., n.d.) 12*s.* 6*d.* net.

To a large extent this book consists of a summary of original researches carried out by the joint authors and published in the *Zeitschrift für anorganische und allgemeine Chemie.* It affords an authoritative account of the principles and practice of spectrographic analysis, and there are chapters dealing with the electrical and optical apparatus used in analysis by the emission spectrum, qualitative analysis, quantitative analysis, experiments on the refinement of the method by photometric intensity measurements, and special problems. Many of the points here presented have hitherto appeared only in the periodical literature. The book is well printed and illustrated, and it will be found helpful and suggestive to all who are interested in spectrographic methods.

An Agricultural Atlas of England and Wales. Second edition, revised. Made on behalf of the Agricultural Economics Research Institute, University of Oxford, by Malcolm Messer. Published by direction of the Ministry of Agriculture and Fisheries. Pp. iv+25+3 maps. (Southampton: Ordnance Survey Office, 1932.) 10*s.* net.

THE present re-issue of this atlas is based on the agricultural returns for 1928. The area of each map now includes the Channel Islands and additional maps show the distribution of agricultural labour, sugar-beet and poultry.

Light and Life[*]

By PROF. N. BOHR, For.Mem.R.S.

AS a physicist whose studies are limited to the properties of inanimate bodies, it is not without hesitation that I have accepted the kind invitation to address this assembly of scientific men met together to forward our knowledge of the beneficial effects of light in the cure of diseases. Unable as I am to contribute to this beautiful branch of science that is so important for the welfare of mankind, I could at most comment on the purely inorganic light phenomena which have exerted a special attraction for physicists throughout the ages, not least owing to the fact that light is our principal tool of observation. I have thought, however, that on this occasion it might perhaps be of interest, in connexion with such comments, to enter on the problem of what significance the results reached in the limited domain of physics may have for our views on the position of living organisms in the realm of natural science.

Notwithstanding the subtle character of the riddles of life, this problem has presented itself at every stage of science, since any scientific explanation necessarily must consist in reducing the description of more complex phenomena to that of simpler ones. At the moment, however, the unsuspected discovery of an essential limitation of the mechanical description of natural phenomena, revealed by the recent development of the atomic theory, has lent new interest to the old problem. This limitation was, in fact, first recognised through a thorough study of the interaction between light and material bodies, which disclosed features that cannot be brought into conformity with the demands hitherto made to a physical explanation. As I shall endeavour to show, the efforts of physicists to master this situation resemble in some way the attitude which biologists more or less intuitively have taken towards the aspects of life. Still, I wish to stress at once that it is only in this formal respect that light, which is perhaps the least complex of all physical phenomena, exhibits an analogy to life, the diversity of which is far beyond the grasp of scientific analysis.

From a physical point of view, light may be defined as the transmission of energy between material bodies at a distance. As is well known, such an energy transfer finds a simple explanation in the electromagnetic theory, which may be regarded as a direct extension of classical mechanics compromising between action at a distance and contact forces. According to this theory, light is described as coupled electric and magnetic oscillations which differ from the ordinary electromagnetic waves used in radio transmission only by their greater frequency of vibration and smaller wave-length. In fact, the practically rectilinear propagation of light, on which rests our location of bodies by direct vision or by suitable optical instruments, depends entirely on the smallness of the wave-length compared with the dimensions of the bodies concerned, and of the instruments.

The idea of the wave nature of light, however, not only forms the basis for our explanation of the colour phenomena, which in spectroscopy have yielded such important information of the inner constitution of matter, but is also of essential importance for every detailed analysis of optical phenomena. As a typical example, I need only mention the interference patterns which appear when light from one source can travel to a screen along two different paths. In such a case, we find that the effects which would be produced by the separate light beams are strengthened at those points on the screen where the phases of the two wave trains coincide, that is, where the electric and magnetic oscillations in the two beams have the same directions, while the effects are weakened and may even disappear at points where these oscillations have opposite directions, and where the two wave trains are said to be out of phase with one another. These interference patterns have made possible such a thorough test of the wave nature of the propagation of light, that this conception can no longer be considered as a hypothesis in the usual sense of this word, but may rather be regarded as an indispensable element in the description of the phenomena observed.

As is well known, the problem of the nature of light has, nevertheless, been subjected to renewed discussion in recent years, as a result of the discovery of a peculiar atomistic feature in the energy transmission which is quite unintelligible from the point of view of the electromagnetic theory. It has turned out, in fact, that all effects of light may be traced down to individual processes, in each of which a so-called light quantum is exchanged, the energy of which is equal to the product of the frequency of the electromagnetic oscillations and the universal quantum of action, or Planck's constant. The striking contrast between this atomicity of the light phenomena and the continuity of the energy transfer according to the electromagnetic theory places us before a dilemma of a character hitherto unknown in physics. For, in spite of the obvious insufficiency of the wave picture, there can be no question of replacing it by any other picture of light propagation depending on ordinary mechanical ideas.

Especially, it should be emphasised that the introduction of the concept of light quanta in no way means a return to the old idea of material particles with well-defined paths as the carriers of the light energy. In fact, it is characteristic of all the phenomena of light, in the description of which the wave picture plays an essential rôle, that any attempt to trace the paths of the individual light quanta would disturb the very phenomenon under investigation; just as an interference pattern would completely disappear, if, in order to make sure that the light energy travelled only along one of the two paths between the source and the screen, we should introduce a non-transparent body into one of the paths. The spatial continuity of light propagation, on one hand, and the atomicity of the light effects, on the other hand, must, therefore, be considered as complementary aspects of one reality, in the sense that each expresses an important feature of the phenomena of light, which, although irreconcilable from a mechanical point of view, can never be in direct contradiction, since a closer analysis of one or the other feature in mechanical terms would demand mutually exclusive experimental arrangements.

---

[*] Address delivered at the opening meeting of the International Congress on Light Therapy, Copenhagen, on August 15, 1932. The present article, conforming with the Danish version (*Naturens Verden*, 17, 49), differs from that published in the Congress report only by some formal alterations.

At the same time, this very situation forces us to renounce a complete causal description of the phenomena of light and to be content with probability calculations, based on the fact that the electromagnetic description of energy transfer by light remains valid in a statistical sense. Such calculations form a typical application of the so-called correspondence argument, which expresses our endeavour, by means of a suitably limited use of mechanical and electromagnetic concepts, to obtain a statistical description of the atomic phenomena that appears as a rational generalisation of the classical physical theories, in spite of the fact that the quantum of action from their point of view must be considered as an irrationality.

At first sight, this situation might appear very deplorable; but, as has often happened in the history of science, when new discoveries have revealed an essential limitation of ideas the universal applicability of which had never been disputed, we have been rewarded by getting a wider view and a greater power of correlating phenomena which before might even have appeared as contradictory. Thus, the strange limitation of classical mechanics, symbolised by the quantum of action, has given us a clue to an understanding of the peculiar stability of atoms which forms a basic assumption in the mechanical description of any natural phenomenon. The recognition that the indivisibility of atoms cannot be understood in mechanical terms has always characterised the atomic theory, to be sure; and this fact is not essentially altered, although the development of physics has replaced the indivisible atoms by the elementary electric particles, electrons and atomic nuclei, of which the atoms of the elements as well as the molecules of the chemical compounds are now supposed to consist.

However, it is not to the question of the intrinsic stability of these elementary particles that I am here referring, but to the problem of the required stability of the structures composed of them. As a matter of fact, the very possibility of a continuous transfer of energy, which marks both the classical mechanics and the electromagnetic theory, cannot be reconciled with an explanation of the characteristic properties of the elements and the compounds. Indeed, the classical theories do not even allow us to explain the existence of rigid bodies, on which all measurements made for the purpose of ordering phenomena in space and time ultimately rest. However, in connexion with the discovery of the quantum of action, we have learned that every change in the energy of an atom or a molecule must be considered as an individual process, in which the atom goes over from one of its so-called stationary states to another. Moreover, since just one light quantum appears or disappears in a transition process by which light is emitted or absorbed by an atom, we are able by means of spectroscopic observations to measure directly the energy of each of these stationary states. The information thus derived has been most instructively corroborated also by the study of the energy exchanges which take place in atomic collisions and in chemical reactions.

In recent years, a remarkable development of the atomic theory has taken place, which has given us such adequate methods of computing the energy values for the stationary states, and also the probabilities of the transition processes, that our account, on the lines of the correspondence argument, of the properties of atoms as regards completeness and self-consistency scarcely falls short of the explanation of astronomical observations offered by Newtonian mechanics. Although the rational treatment of the problems of atomic mechanics was possible only after the introduction of new symbolic artifices, the lesson taught us by the analysis of the phenomena of light is still of decisive importance for our estimation of this development. Thus, an unambiguous use of the concept of a stationary state is complementary to a mechanical analysis of intra-atomic motions; in a similar way the idea of light quanta is complementary to the electromagnetic theory of radiation. Indeed, any attempt to trace the detailed course of the transition process would involve an uncontrollable exchange of energy between the atom and the measuring instruments, which would completely disturb the very energy transfer we set out to investigate.

A causal description in the classical sense is possible only in such cases where the action involved is large compared with the quantum of action, and where, therefore, a subdivision of the phenomena is possible without disturbing them essentially. If this condition is not fulfilled, we cannot disregard the interaction between the measuring instruments and the object under investigation, and we must especially take into consideration that the various measurements required for a complete mechanical description may only be made with mutually exclusive experimental arrangements.

In order fully to understand this fundamental limitation of the mechanical analysis of atomic phenomena, one must realise clearly, further, that in a physical measurement it is never possible to take the interaction between object and measuring instruments directly into account. For the instruments cannot be included in the investigation while they are serving as means of observation. As the concept of general relativity expresses the essential dependence of physical phenomena on the frame of reference used for their co-ordination in space and time, so does the notion of complementarity serve to symbolise the fundamental limitation, met with in atomic physics, of our ingrained idea of phenomena as existing independently of the means by which they are observed.

(*To be continued.*)

Phases in South African Locusts

THE theory of phase variation in swarming locusts was first put forward about ten years ago, since when a considerable amount of data has been accumulated in its support. Most of the evidence, however, was either based on direct field observations, or on small-scale experiments which served only to prove the fact of the transformation from the solitary to the gregarious phase, and vice versa, but were insufficient for analytical study of the phenomenon and of its underlying causes. This gap has now been filled by a paper by Prof. J. C. Faure recording the results of four years' experimental studies on the phases of four species of locusts occurring in South Africa.*

The bulk of the experiments refer to the well-known brown locust of South Africa (*Locustana pardalina*, Wlk.), and most of them were repeated on the tropical migratory locust (*Locusta migratoria migratorioides*, R. and F.) which swarmed over enormous areas of the African continent last year; some corroboration of the results was obtained also from studies on the desert locust (*Schistocerca gregaria*, Forsk.) and the red locust (*Nomadacris septemfasciata*, Serv.).

The main result of the numerous breeding experiments made under a great variety of conditions is a final proof that the phase transformation is a scientific fact which can no longer be doubted. Indeed, Prof. Faure succeeded in producing the swarming phase from the solitary one, and vice versa, in the case of every species experimented upon.

Turning to the problem of the mechanism and the causes of the transformation, Prof. Faure's experiments confirm beyond doubt the importance of the density of the population in a given space. Locusts raised in crowded cages invariably assume the colour and structural characters of the swarming phase, and those kept in isolation become typical of the solitary phase. The factor responsible for the transformation appears to be the greater activity on the part of locusts in crowded cages, where every movement of an individual disturbs the others and the mutual excitation practically never dies down. This excessive activity results in an abnormally high rate of metabolism, and the striking reddish (or yellow) and black coloration of the hoppers of the swarming phase may be ascribed to the deposition in the chitin of some products of this abnormal metabolism; these unknown products are called 'locustine' by Prof. Faure. Structural differences by which the two phases can be separated may be explained also as a result of greater development of certain muscles in gregarious hoppers as compared with the solitary ones. This theory was tested in a series of experiments in which hoppers kept in isolation were forced to excessive activity, but unfortunately this proved to be a very difficult task, since none of the several very ingenious methods of stimulation applied to hoppers produced the desired degree of activity. Nevertheless, the results show clearly that a change towards the gregarious phase occurs in isolated but active hoppers, and there remains little doubt that solitary hoppers if forced to lead an excessively active life would produce a locust of the swarming phase.

A supplementary factor of the transformation is temperature, since the gregarious phase is obtained more easily and is more typically developed at higher temperatures. This is also in keeping with the above theory, since the general activity of hoppers is greatly affected by temperature conditions.

The results of some experiments suggest that transformation is caused not only by direct environmental influence on the developing individual, but that the conditions of adult life may also have an effect on the characteristics of the progeny. Thus, the progeny of adults of the gregarious phase show certain characters of that phase already in the first instar; Prof. Faure suggests that this is not a case of the inheritance of phase characters, but that the phenomenon may be due to the 'locustine' being handed down to the progeny in the nutritive yolk of the eggs. Indeed, a series of crossing experiments proved that phase characters are not Mendelian characters, and disposed effectively of some earlier suggestions in that direction.

An interesting point is raised by Prof. Faure's experiments on the coloration of solitary hoppers. As a rule, such insects are rather variable in colour but often exhibit a close correlation with the colour of the surroundings. The breeding of hoppers in uniformly painted boxes resulted in many cases in excellent general imitation of the background, even of the white, or black one.

---

* "The Phases of Locusts in South Africa". *Bull. Entom. Res.*, **23**, pt. 3, 1932, 112 pp., 25 pls., map.

These experiments throw an interesting light on the problem of the so-called sympathetic coloration in insects, and suggest a promising line of research. It was, however, somewhat unexpected that the green colour of environment is not imitated by hoppers, though they often become green on almost any background. Detailed experiments on the production of green coloration showed that it develops when hoppers are kept in a humid atmosphere and supplied with abundant moist food. However, attempts to discover chlorophyll in green hoppers failed, and the problem awaits further investigations.

Another interesting point raised with regard to the brown locust is the ability of its eggs to lie dormant for extremely long periods, up to 37 months after oviposition. A number of other equally interesting and important observations and experiments are recorded in the paper, which contains also a discussion of the bearing which these laboratory results have on the actual locust problem in the field. The knowledge of the phase transformation is already applied in practice in South Africa, and a careful watch for incipient congregations of solitary locusts in the field is kept. All such congregations are destroyed, with the result that the swarming phase has not appeared for several years. Further field ecological work will help in defining more precisely the areas favourable for the production of the swarming phase, and this will facilitate the anti-locust work still more, placing it entirely on the basis of prevention of outbreaks.

Prof. Faure's paper is exceptionally well documented by exact descriptions of experiments, tables of results and extremely well-reproduced coloured plates showing the remarkable range of the variation connected with the phase transformation of the species discussed. The results recorded constitute a great advance in our knowledge of the locust problem, and, moreover, they should go far towards demonstrating to biologists in general the outstanding interest of these insects, on which a number of fundamental problems can be studied better than on any other material.

B. P. UVAROV.

Obituary

PROF. JOHANNES SCHMIDT

THE science of oceanography has lost one of its most outstanding leaders by the death of Prof. Johannes Schmidt, director of the Carlsberg Physiological Laboratory, which occurred at Copenhagen on February 22 at the age of fifty-six years. His loss will leave a host of friends and colleagues all the world over with a sense of personal bereavement and regret, for being himself a great traveller with his home in Copenhagen, the headquarters of the International Council for the Exploration of the Sea, with which he was intimately associated, he was in close and frequent contact with all who were interested in the science of the sea. He was a man of quite exceptional charm, with a genius for friendship, always eager to help the work of others and to appreciate any help which others could give him in the execution of the bold schemes of research which he planned.

The name of Johannes Schmidt will no doubt be chiefly remembered for his solution of the age-old mystery of the life-story of the eel, but this success represented but a small part of his scientific activities and personal achievement. His versatility and breadth of view were striking. Starting his career as a botanist, his first expedition was to Siam in 1899, when he was editor and joint author of a report on "The Flora of Koh Chang". In 1910 he began at the Carlsberg Laboratory a series of investigations on hops (*Humulus lupulus* Linn.), publishing reports on their growth, biochemistry, and occurrence in the wild state in Denmark, and superintending researches on their fertilisation, development and the production of hybrids.

Later, under the inspiring influence of the late Dr. C. C. Joh. Petersen, and helped no doubt by his own enthusiasm for the sea—for first and last and always he was a good sailor-man—Schmidt became attached to the scientific staff which was carrying out Denmark's share of the programme of the International Council for the Exploration of the Sea. The importance of the fisheries at Iceland and the Faroes caused the Danish research vessels to go farther afield than those of the other powers, and the steam trawler *Thor* carried out regular cruises from Copenhagen to the northern waters of the Atlantic.

This was Schmidt's training ground for the extended expeditions in small vessels which he eventually undertook. At first he concentrated on the description of post-larval and early adult stages of fishes, especially of the cod family, and their distribution and migrations in relation to temperature and other physical characteristics of the sea-water. This was necessary pioneer work which has stood the test of time.

In May, 1904, Schmidt was collecting young fishes with large pelagic nets, and captured in the North Atlantic west of the Faroes one specimen of the *Leptocephalus brevirostris*, which Grassi and Calandruccio in 1896 had proved to be the larva of the common fresh-water eel. In the following year (1905) the *Thor* succeeded in capturing, at the end of May, a small number of specimens of *Leptocephalus* over the deep water off the west of Scotland, and still farther south the numbers increased over depths of 1,000–1,500 metres, until, in water of this depth in the central part of the plateau off the mouth of the English Channel, up to 70 per two hours' haul were obtained with nets towed with about 300 metres of wire. A few hauls taken in September, west of the Hebrides, showed that the larvæ were already beginning to metamorphose, and would soon completely change into elvers or glass-eels.

To determine where the eels actually spawned it remained to find the earliest larval stages and the eggs. This involved a search extending all over the whole southern and western part of the North Atlantic. Only after years of persistent effort was it possible to reach a full and satisfactory solution of this aspect of the problem. Successful cruises were made in the *Thor* to the Straits of Gibraltar and the Mediterranean (1908–10). Arrangements were made with Danish ship-owners for nets to be towed from steamers crossing the Atlantic by different routes. In 1913 a small sailing schooner, the *Margrethe*, was equipped and cruised in the Atlantic as far as the West Indies, when it was found that the smallest sizes of the larvæ were all taken west of a line drawn from Newfoundland in a south-easterly direction towards Cape Verde. In 1920 a large schooner, the *Dana*, replaced the *Margrethe*, which had been wrecked. After two years it became possible to map out the breeding grounds by a study of the distribution of the earliest larval stages, less than 10 mm. in length, which had all been taken in a comparatively small area, the centre of which lay midway between the Leeward Islands in the West Indies and Bermuda. By these researches Schmidt may be said to have solved the main problem of the life-history of the eel.

With this extension of his cruises into the Atlantic Ocean, the scope of Schmidt's oceanographical work became enormously enlarged, and had developed into an important study of the great oceans. The Danish Government secured a large steam trawler, also named *Dana*, and equipped her as a research vessel. In this ship he undertook a number of voyages in the Atlantic Ocean, the Pacific and the Mediterranean, and finally made the great two years' voyage around the world in 1928–30, an account of which he published in NATURE of March 21 and 28, 1931.

Schmidt's study of the geographical distribution and life-histories of fishes led him, at an early date, into researches on fundamental biological problems concerning the nature of species, of races and of heredity, and his success as a biometrician and as a student of genetics was almost as striking as that which he achieved in oceanography. Biometrical studies on races of fish had formed a feature of his early work on gadoids and eels. Later, in a series of papers published between 1917 and 1922 in the *Comptes-Rendus* of the Carlsberg Laboratory and in the *Journal of Genetics*, the subject was developed on both statistical and experimental lines. Striking results were obtained with the viviparous blenny (*Zoarces*). He was able to show that in some of the Danish fiords the average number of vertebræ in populations of this fish living at the upper ends of the estuaries is significantly lower than that of the populations in the estuary mouths, the latter again being lower than that of populations living outside in the Kattegat. The averages varied progressively from 108·0 to 117·3. The question whether these fluctuations were due to heredity or to environment, or to both these factors, was made the subject of a well devised series of experiments. A comparison of the average number of vertebræ in 857 mothers, with the corresponding number in 8,570 individuals of their offspring, showed that the values for the offspring continuously increased as the maternal numbers increased from 107 to 119. The conclusion was drawn that such a conformity could not appear if the number of vertebræ in an individual were determined by the environmental conditions existing during development alone. The number of vertebræ must therefore be, in part at any rate, a hereditary character. Experiments were then made by keeping samples of 300 specimens of each of two different populations of *Zoarces* in an enclosed area near the mouth of Ise Fiord in large, perforated wooden boxes, with the result that the difference in the numbers of vertebræ in the two populations did not disappear in the offspring. On the other hand, two samples of the same population, allowed to develop under different environmental conditions, did show a smaller, but significant difference in the number of vertebræ of the offspring.

In continuation of work on race problems, Schmidt carried out many breeding experiments on trout, and on the fresh-water tropical fish *Lebistes reticulatus*, as well as on poultry.

Such a wide and varied field of fruitful effort leads one to ask, what qualities in the man lay at the root of his success ? First, I think, a broad, clear outlook on the problems he hoped to solve was followed by a bold but simple and straightforward plan of attack : then, steady, hard, persistent work, carried on year after year with no turning aside, every detail carefully thought out, every operation accurately performed until at last the answer came. He was a fine organiser and knew how to get the best from those who helped him. The brilliant school of young marine biologists in Denmark, who will continue the work that he began, is his true memorial.

E. J. ALLEN.

DR. ALFRED RÉE

IN the death of Dr. Alfred Rée at Withington on February 26, at the age of seventy years, both chemical industry and the profession of science lose an acknowledged leader and one whose wide outlook and sympathy had won universal respect. Dr. Rée was born at Leeds and educated at the Bradford Grammar School and later at the Universities of Geneva and Munich. He was a Doctor of Philosophy of the University of Berne and had travelled widely on the Continent and in the United States, to which circumstance no doubt his interest in international affairs was partly due. He was a warm supporter of Lord Derby when he was forming the English

Speaking Union and many Americans found a genuine welcome at Dr. Rée's house.

Dr. Rée entered business as a dyestuffs manufacturer and was proud of a connexion through Claus Rée and Co. at Clayton with Brooke, Simpson and Spiller, who were successors of Simpson, Maule and Nicholson, and Perkin and Sons, the original manufacturers of mauve. Although he retired from the industry in 1907, he retained many and varied interests in dyestuffs and other branches of chemical industry and was a director for some years of the British Dyestuffs Corporation. He is probably best known for his work for the Manchester Chamber of Commerce; early in his life he was vice-chairman of the chemical section and he played a prominent part in securing reform of the patent laws. Elected a director of the Chamber in 1910, he was made president in 1924–25. He was one of the founders of the Association of British Chemical Manufacturers and served on its Council for several years, being still an honorary member at the time of his death.

With these industrial and commercial interests, Dr. Rée combined a keen interest in education and long served the University of Manchester as treasurer and deputy treasurer. He was for many years chairman of the chemical section of the College of Technology and served on the Manchester Education Committee from 1910 until his death. He was elected a fellow of the Institute of Chemistry in 1918 and served on its Council in 1927–30. He took an active interest in the formation of the British Association of Chemists in 1917 and served as its first chairman. He was one of the oldest members of the Society of Chemical Industry and was a vice-president in 1919–21. He also served as president of the Society of Dyers and Colourists in 1916–17 and his presidential address to that Society is a fine example of his wide outlook and mature judgment.

Few scientific workers have indeed displayed such a fine capacity for public as well as personal service and only Dr. Rée's modesty prevented him from being better known. He was singularly free from ambition and was a most approachable man in spite of his many interests. A quiet but tenacious personality and a rare capacity for impartial judgment won him wide popularity as well as respect, and his indefatigable industry leaves a place among the country's industrial and professional leaders which will be hard to fill.

R. B.

Sir Benjamin Gott

Sir Benjamin Gott, who died on February 26 at the age of sixty-seven years, was one of the group of distinguished educational administrators whose careers virtually began with the passing of the Education Act, 1902. Sir Benjamin held the office of Secretary to the Middlesex Education Committee from 1902 until 1928; he was appointed Organising Inspector of Technical Education in Middlesex in 1898, and, at the date of his retirement, had completed thirty years' service as Education Officer to the Middlesex County Council.

Benjamin Scaife Gott was born at Bingley and became a foundation scholar of Bradford Grammar School. Thence he passed as a scholar to Gonville and Caius College, Cambridge, where he took a first class in Part I and a second class in Part II of the Natural Sciences Tripos. After three years on the staff of Wesley College (now King Edward VII School), Sheffield, he became science master at Cheltenham Grammar School, where he had Sir Robert Blair, afterwards Education Officer to the London County Council, and Mr. E. Salter Davies, Director of Education for Kent, as colleagues. He also acted as Principal of the Cheltenham School of Science.

His duties in Middlesex were at first confined to technical education—the opportunity for the full exercise of his great gifts as an administrator came with the Education Act, 1902, by which the County Council became the higher education authority for the whole of the Administrative County and the elementary education authority for an area containing about one-third of its population. It was Sir Benjamin's ambition to create a system of secondary schools which would make higher education available for all boys and girls of ability, however poor the circumstances of their parents. He had the satisfaction of seeing his ambition realised before he retired. In the interval between 1902 and 1928, the County Council had provided thirty-four new secondary schools and the number of pupils in attendance had increased from 700 to 18,000. In 1898 the Middlesex authority spent £7,000 on education; in the last year of his service, the authority's expenditure was nearly £1,500,000.

Sir Benjamin was, for some time, a member of the Consultative Committee of the Board of Education, the Adult Education Committee, and the Burnham Secondary and Technical Committees. After the War he rendered valuable service as Divisional Director of Industrial Training in connexion with the Ministry of Labour's scheme for the training of disabled ex-Service men. In 1924 he received the honour of knighthood in recognition of his services to education.

Soon after he retired, Sir Benjamin became chairman of the Commission on Educational and Cultural Films. A few weeks before his death he accepted the chairmanship of the Unemployment Committee of the National Council of Social Service, and in order to free himself for the onerous duties of this position, he resigned his membership of the governing bodies of the Northern Polytechnic, University College School and the Maria Grey Training College. This work took him to Bolton the day before he died. Whilst presiding at a conference of voluntary workers, he was overcome by a fainting attack, which was followed by a fatal seizure early the next morning.

MR. W. McWHIRTER

MR. W. McWHIRTER, who died at Glasgow on March 6, at the age of eighty-two years, was one of the pioneers of the electrical industry. In 1882 he invented the first instruments for indicating volts and amperes and these he continually developed, introducing magnetic shielding and other devices into his ammeters and voltmeters. His electrical water-level indicators and recorders fulfilled a most useful function.

Apprenticed to his uncle in the bakery and confectionery business, McWhirter spent nearly all his leisure experimenting on magnetism and electricity. He joined the Glasgow and South Western Railway, where he attained the position of divisional inspector. He then joined the Barrow and Furness Railway and was partly responsible for one of the earliest installations of dock lighting by means of arc lamps at Barrow. He was also responsible for the first electric lighting installation at the Glasgow Central Station. In those days the arcs were not well shaded, so that the light was dazzling and cast such dark shadows that one had to walk warily. After lighting the Central Station, McWhirter started business in Glasgow and, later on, opened the Faraday Electrical Engineering Works in Govan, where important improvements were made in the efficiency and commutation of the dynamo.

Mr. McWhirter was well known to all the older generation of electrical engineers and had many friends. He was one of the founders of the Electrical Contractors' Association in Scotland and was chairman of the Scottish centre of the Institution of Electrical Engineers in 1912. In the course of his electrical researches he co-operated with Silvanus Thompson, Ayrton and Perry. One of his pupils was Dr. A. Hay, who was a professor at Coopers Hill and afterwards at the Indian Institute of Science, Bangalore.

WE regret to announce the following deaths:

The Duke of the Abruzzi, Founder's medallist of the Royal Geographical Society in 1901, who was known for his explorations in the Far North, in Africa and in India, on March 18, aged sixty years.

Prof. W. C. Unwin, F.R.S., emeritus professor of engineering in the Central Technical College, City and Guilds of London Institute, president of Section G (Engineering) of the British Association in 1892, of the Institution of Civil Engineers in 1911, and of the Institution of Mechanical Engineers, on March 17, aged ninety-four years.

News and Views

Early Man in East Africa

ON March 18–19 a conference summoned by the Royal Anthropological Institute met at St. John's College, Cambridge, under the presidency of Sir Arthur Smith Woodward, to receive reports on the human skeletal remains discovered by Dr. Leakey's archæological expedition to East Africa in the autumn of last year. On the geological, palæontological, archæological and anatomical evidence, the findings of the respective committees are :—(1) That it is clear that the two fragments said to have been found *in situ* at Kanjera belong to the original deposit and that the fragments cannot have been introduced into the calcareous deposits at a later date ; (2) that the fragment of human lower jawbone from Kanam is derived from a deposit of lower Pleistocene age, while the fauna from the Kanjera deposits, in which the cranial fragments were found, cannot be later than the middle Pleistocene ; (3) that the cranial remains from Kanjera show no character inconsistent with reference to the type of *Homo sapiens*, special points noted being the absence of any frontal torus and a thickness of bone not present in any non-pathological modern skull and comparable with that of the Piltdown and Boskop skulls : while the Kanam jaw shows no appearance incompatible with its inclusion in the type of *Homo sapiens* or with the high antiquity assigned to it ; and (4) that the Kanam jaw is associated with a pebble industry, comparable to Oldoway Bed I, which has no precise counterpart in western Europe ; and the Kanjera skull with a Chellean industry corresponding with that of the upper part of Oldoway Bed II, the pebble industry of Bed I being older than the Chellean industry from Bed II, while the latter corresponds typologically to industries from deposits of early Pleistocene age in Europe.

Indian Federation

WITH the publication of the White Paper, discussion of the future government of India enters on its final phase. At this stage it would be vain to expect that any fundamental change will be made in the basic principles upon which the proposed constitution has been framed. For good or for ill, a matter on which time alone will give a ruling, the principles of Western democracy, which themselves in the West are now being strained to breaking point, will be applied to an Eastern community, or rather communities, in which the elements, especially that of Hinduism, as past experience has shown, are further removed in temperament from the spirit of compromise, which is of the essence of democracy, than almost any other community in the world. Hinduism as a social and religious system has shown in the past an almost unlimited power of assimilating elements from outside, but it is itself incapable of adaptation. Even the influence of Mr. Gandhi has not availed to modify the position of the Untouchables, notwithstanding the political gain that thereby would have accrued to Hinduism. However flattering the abortive results of Mr. Gandhi's efforts to the opinion of the scientific observer, he regretfully accepts this as further confirmation of his view that native institutions alone, and not the restricted individual franchise, could attain in India the desired end of government by consent of the whole people.

Metropolitan-Vickers Representatives in Russia

AT our request, the Metropolitan-Vickers Electrical Co., Ltd., has been good enough to send us the following particulars of its technical representatives, whose recent arrests in Russia have been the subject of a number of questions in Parliament: Mr. Allan Monkhouse, M.I.E.E., A.M.I.Mech.E., who is at present manager in Russia for Metropolitan-Vickers Electrical Export Co., was for several years a senior member of the staff of the Research Department, devoting his interest more particularly during those years to problems on insulation. In addition to his contributions to the scientific press, Mr. Monkhouse wrote "Electrical Insulating Materials" published in 1926. Mr. L. C. Thornton, A.M.I.E.E., left Trafford Park in 1924 to go out to Russia on erection work for Metropolitan-Vickers and has for a number of years been in charge of all erection work in Russia. Mr. J. Cushny, B.Sc.(Eng.), A.M.I.C.E., A.M.I.Mech.E., served his apprenticeship with Metropolitan-Vickers and after serving on the erection staff in Russia for some years, was appointed senior assistant to Mr. Thornton. Messrs. W. L. MacDonald, A. W. Gregory and C. H. de Nordwall, all of whom joined the firm between 1920 and 1922, have been engaged in erection work in Russia for some considerable time. The Metropolitan-Vickers Export Co. has now been supplying plant and machinery to the U.S.S.R. for the last ten years. For the latter part of this time it has had, in addition, an agreement under which technical information and supervision has been supplied by the Company to the U.S.S.R. which has been building the Company's turbines under licence. This agreement is one of the results of the leading position in the field of turbine engineering occupied by the Company, and the agreement has for the last few years been extended to cover the design and manufacture of heavy electrical plant.

Aeronautics and the Royal Air Force

SIR PHILIP SASSOON, M.P., Under Secretary of State for Air, in his air estimates speech in Parliament on March 14 offered a good deal of congratulation to the technical and scientific side of the aeronautical community in Great Britain, in that it has managed to maintain progress and extended activities in spite of a progressive reduction in its expenditures. Special tribute was paid to Sir Richard Glazebrook, who retires at the end of this month from the chairmanship of the Aeronautical Research Committee, where he will be succeeded by Mr. H. T. Tizard, rector of the Imperial College of Science and Technology. Sir Richard has been associated with the scientific side of aeronautics since 1909, and has been chairman of the Aeronautical Research Committee since its formation thirteen years ago. Speaking of the Royal Air Force, Sir Philip said that no new squadrons are being formed, although it is still ten short of the 1923 approved programme, and is closing one flying training school. In spite of reductions it has rendered both direct and indirect assistance to the administration of law and order in the more backward of the Empire territories overseas. The suppression of turbulent tribes, transporting of British troops to stiffen up disaffected native levies, giving flights to political agents and local chiefs in areas in which the inhabitants still held that aircraft were a myth, making a flight over the Himalaya range in 2 hours 20 minutes, which normally needed a 17 day march, are among the direct activities mentioned.

THE humanitarian and less directly productive work carried out by the Royal Air Force during the past year is equally striking. Supply of medical services, flood warnings, surveying, fishery protection, locust fighting, famine relief, mail carrying to isolated communities, have absorbed as much as 40 per cent of the flying time of some of the Middle East squadrons. The making of record flights, such as the recent long distance to the Cape, which now brings the records for speed, height, and distance to British aeronautics, is not without its indirect value to Great Britain's prestige. A new system of subdivision of duties amongst R.A.F. mechanics will make considerable saving in the cost of personnel without affecting the technical efficiency of the aircraft maintenance. This is due to the complete change over to all-metal aircraft. Dealing with civil aviation, Sir Philip referred to the continued expansion of Imperial Airways and promised the Indian extension of the Australian air route during 1933. Air passenger traffic has increased by more than 100 per cent on European, and more than 50 per cent on other Empire, routes.

The Panda at the Zoological Gardens

THE carnivores are really a very remarkable group, ranging in size from the tiger to the weasel, and presenting singular contrasts in the matter of shape. Nor are they all flesh-eaters, some being almost exclusively vegetarians, and one, the kinkajou, has developed a prehensile tongue, like an ant-eater, and a prehensile tail like a spider-monkey. The shape of the body has been moulded by adjustment to their feeding habits. Some have become burrowers, some arboreal, and some aquatic. Their coloration has in like manner been governed by this same factor of food-hunting which of course determines their environment, as witness the polar bear, the tiger, the leopard, and the Cape hunting dog. But there are many other and less familiar types of coloration. Among these is the singular panda (*Aelurus fulgens*), a recent arrival at the Zoological Gardens, Regent's Park. It is a creature which cannot fail to attract the attention of visitors owing to its striking coloration. A native of the south-eastern Himalayas, where it lives among rocks and trees at a height of 7,000-12,000 ft., its habits, and the relation thereto of its coloration, have never been the subject of careful observation. Placed under relatively natural surroundings—which is becoming more and more a distinctive feature of the Gardens—some useful information may be gleaned on this head.

As touching the coloration of the panda in relation to its haunts, we have little to build on at the moment, for while some tell us it is found among the rocks, others tell us that it is arboreal. Probably it affects both environments as circumstances may determine. The racoons, to which tribe it belongs, display a similar versatility. The general hue of the upper part of the body is of a lively chestnut-red, with white markings on the face, while the legs and belly are black. The tail, nearly as long as the body, displays the rings characteristic of the racoon. Since it is largely a vegetarian, with a fondness for fruit, this coloration must be regarded as protective: and it may bear some relation to the positions assumed during sleep when protection of this kind is most needed. But here again we are in need of further observation; for it is said to sleep coiled up like a cat with the bushy tail over its head, but at other times resting on its haunches with the head tucked under the chest, and between the fore-legs, after the manner said to be common with the racoons. Here, surely, is a matter which can be settled at the Gardens.

Photoelectric Exhibition at the Science Museum

A SPECIAL exhibition devoted to photoelectric cells and their practical applications will be opened at the Science Museum, South Kensington, on March 25, and will remain on view for three months. Photoelectric cells are now being widely applied both in pure science and in industry, and the exhibition is intended to give an illustration of the great variety of these applications. Besides exhibits showing the construction of the three main types of light-sensitive cell, some simple working experiments have been arranged to demonstrate their properties and to illustrate some of the methods of amplifying the small currents yielded by the cells under varying illuminations. The practical applications of photoelectric cells can be roughly classified into those involving only the detection of light and those involving its measurement. The first class is illustrated in the exhibition by a number of working models showing the use of the cells, for example, for counting small packages on a conveyor belt, and in burglar alarms, while, as an illustration of the way in which a comparatively large amount of power can be controlled, there is a door which is automatically opened whenever a certain beam of light is interrupted by the visitor. Applications involving the measurement of light intensity are also illustrated. These include the measurement of daylight or of indoor lighting, the automatic switching of street-lamps, and the measurement of the density of factory smoke, while the ability of photoelectric cells to respond to rapidly fluctuating light is shown by their well-known applications in the reproduction of sound from sound-films, and their use in television.

Early American Bridges

AT a meeting of the Newcomen Society held at the Caxton Hall, Westminster, on March 15, Capt. L. N. Edwards, of the United States Bureau of Roads, read a paper on "The Evolution of Early American Bridges" in which he dealt with the work of the bridge pioneers of America down to the time of the Civil War of 1861–65. All the early settlements, he said, were situated on sheltered bays, tidal inlets or navigable streams and "the water was the first American highway". When roads came to be constructed, it was natural that the necessary bridges should be simply tree trunks felled at the site. Transportation developments were a challenge to those engaged in bridge building and the art of carpentry became of immense importance. In the eighteenth century, pile and trestle bridges came into use and these were followed by arched and trussed structures, some of great span. The Upper Ferry Bridge over the Schuylkill River built by Louis Wernag in 1812 had a wooden arch of 340 ft. span and the McCalls Ferry Bridge over the Susquehana River built by Theodore Burr in 1814 had a central span of 364 ft. Especially important were the trusses patented by Ithiel Town, 1820, Col. S. H. Long, 1830, William Howe, 1840 and the two Pratts, 1844. A wrought-iron chain suspension bridge was built by James Finley in 1801, while in 1842 Col. Charles Ellet built the first wire suspension bridge in America. Cast iron was successfully used for a bridge in 1836. Sixty-seven patents for bridges were issued by the United States Patent Office between 1797 and 1860. The first books on bridge work were by Herman Haupt, 1842, and Squire Whipple, 1847. Capt. Edwards's paper, which was illustrated with many lantern slides, is a notable addition to the history of the subject of American bridges.

Cosmic Radiation

IN his Symons Memorial Lecture delivered before the Royal Meteorological Society on March 15, Mr. P. M. S. Blackett dealt with "Cosmic Radiation". The study of what is now known as cosmic or penetrating radiation began more than thirty years ago with the experimental investigation of the conductivity of the air in closed vessels. By 1932, measurements of the ionisation had been carried out up to heights of 28 km. in the atmosphere and down to depths of 230 m. under water. The ionisation is found to be 100,000 times more intense at the highest point reached compared with that at the greatest depth. More than four hundred papers have been written on the subject and still the nature of the primary radiation is not certain and its origin quite unknown. The ionisation is constant in time to within two per cent at any one place, but is about twelve per cent less intense at the equator than in latitudes of 50° N. and S. From these latitudes to the poles it is nearly constant. It is probable, but not certain, that the primary radiation incident on the earth's atmosphere consists of an isotropic corpuscular radiation with a mean energy of more than 10^{10} volts. The actual ionisation at sea level is due to fast particles, mainly electrons, protons and 'positive electrons'. The tracks of these particles can be photographed by the cloud method and such photographs have shown that very complex phenomena of great variety and interest occur in connexion with the absorption of the primary cosmic rays by matter.

Museums of British Territory in Africa and the Mediterranean

HARD on the heels of the report on Canadian museums by Sir Henry Miers and Mr. S. F. Markham, which was reviewed in NATURE of January 21, p. 84, comes the same authors' "Report on the Museums and Art Galleries of British Africa" together with a "Report on the Museums of Malta, Cyprus and Gibraltar by Alderman Chas. Squire and D. W. Herdman". The report is accompanied by a "Directory" (price 5*s.*) of all these museums, and of those of Mauritius, constituting the third volume of the "Directory of Museums" being published by the Museums Association. To visit the forty museums of Africa was a strenuous enterprise even with all the resources of modern transport. Those museums cover a wide range in quality and administration as well as in distribution, from the fine South African Museum in Cape Town to the poor apology for a scientific museum, which, as the authors say more than once, is unworthy of that rich city Johannesburg. Poverty coupled with handsome buildings are the characteristics of the South African museums—a combination not unknown in other lands. Their chief needs are said to be "greater financial security, some forms of active co-operation between all museums, and the development of educational work".

THE museums of the East African and West African territories are barely out of the shell, so that the reporters can do little more than tender good advice. The Coryndon Museum at Nairobi and the Zanzibar Museum are the only institutions worthy to be called public museums. Over areas to be measured in millions of miles, museums are needed to fulfil what is still the first purpose of a museum—the preservation of objects that would otherwise be lost, and nowhere is civilisation more destructive than in Africa. The Mediterranean museums present different problems, but here too it is this primary function that comes first in the report, as shown by its insistence on permanent curators, a higher standard of curatorship, protection against fire, and cases that will keep out dust and insects. The value of these reports to the museums concerned, and the usefulness of the directories to those elsewhere, can scarcely be exaggerated. That on Canada is already fruitful of results; though its criticism was severe, its expression was tactful and it has aroused no resentment but rather a determination to profit by it. Great credit and warm thanks are due to the Museums Association which does the work and to the Carnegie Corporation which provides the funds.

Measurement of Chimney Smoke

MAJOR C. E. PRINCE gave an interesting lecture to the Junior Institution of Engineers on February 24 on the practical applications of light-sensitive apparatus. The effects produced by a beam of light when projected on vapours, the particles of which, like drops of water, are possessed of reflective and refractive powers, have to be studied. The most useful effect for observation is the deflection or scattering of the beam. In the case of smoke, the interruption of the light by the particles of carbon gives the easiest and best method of measurement. Major Prince showed apparatus in which a beam projected through smoke and then on to a light-sensitive element gave a continuous quantitative record on a moving chart of the diminution of light due to the smoke. One difficulty was to interpret the readings in terms of a definite unit as the cut-off varies with the depth of the column penetrated by the light. The problem is of importance as it gives a method by using indicating or recording instruments for proving or refuting a contention that excessive smoke was being or had been allowed to issue from industrial chimneys. The present method of visual observation and comparison with a Ringelmann screen at the chimney top takes little or no account of the size of the chimney and consequently of the volume apart from the density of the issuing smoke. It neglects also the direction of the wind and its effect upon the apparent density of the smoke. It is necessary to define more accurately the density of smoke at a given distance. By using a selenium or a photoelectric cell, this is possible. It remains for those who have the managing of smoke-producing units and those who apply the regulations governing smoke nuisance to agree on a standard method.

National Institute of Agricultural Botany

ONE of the ways in which the Government in Great Britain is aiding agriculture is through grants made to the National Institute of Agricultural Botany. This Institute is doing very important work for the farming community by testing seeds and by encouraging the use of better varieties of plants. The thirteenth annual report, which has just been published, states that the record number of 30,680 samples of seeds was tested in the year ended July 31, 1932, at the Official Seed-testing Station. Trials with oats showed that one variety, Golden Rain II, gave the best results, although it is not widely grown; and that in Wales the variety popularly believed to be the best (Record) was significantly inferior to the three other varieties tested. The outstanding problem in the home beet-sugar industry is to improve the yields of beet and of sugar per acre; whereas the average for Europe is about 1½ tons of sugar per acre, in Great Britain it is only slightly more than 1 ton. The Institute has been attacking this important problem and has demonstrated how much these yields depend upon the variety grown. Trials extending over three years have shown differences of nearly 20 per cent between varieties in use by farmers, and Kleinwanzleben *E* has in general been found to be by far the best; at one centre it gave no less than 3 tons of sugar per acre. As a result of this work, it is now possible to recommend twelve different strains for use in the British Isles. Other activities of the Institute include the provision of pure stocks of cereal seed, the improvement of varieties of potato in respect of yield, and, especially, of immunity from disease, and the prevention of the use of more than one name for the same variety.

Minimum Climatic Temperature

A RECENT note by C. F. Talman of the United States Weather Bureau, one of the "Why the Weather?" series issued by Science Service, Washington, D.C., describes an observation of some interest for those who attach importance to climatic extremes. The note states that when Archdeacon Stuck climbed Mount McKinley, Alaska, in 1913, he placed a minimum thermometer in a small wooden case and fastened it securely in a cleft of rock at a height of 15,000 feet above sea level. When the thermometer was recovered last May, it was found that the index was down in the bulb, and indicated a minimum at least as low as −100° F. Mr. Talman finds it difficult to say how much confidence can be placed in the observation; one possibility suggested is that vibration due to strong wind caused the index to fall below what should have been its lowest position. According to the 1930 edition of the "Meteorological Glossary" of the Meteorological Office, Air Ministry, the lowest temperature recorded at the earth's surface is −93·6° F. at Verkhoïansk, Siberia, on January 3, 1885. There is now at least one colder place in Siberia than Verkhoïansk equipped as a climatological station; such a place would probably have yielded a lower reading than −93·6° had it been in operation in 1885. In the free air, much lower readings have been recorded at greater heights in low latitudes, where the normal fall of temperature with height is maintained to such high levels that in spite of the relative warmth near the ground a lower temperature is recorded than at any height in temperate or high latitudes. The "Meteorological Glossary", for example, refers to a reading of −131·6° F. obtained at a height of about 54,000 feet above Batavia, Java.

Archæology and Tradition

THE Sir John Rhys memorial lectures of the British Academy, inaugurated in 1925 and delivered annually since that date, have now secured, as a series, a place in Celtic studies worthy of the great scholar they commemorate. The lectures have been apposite in subject and the lecturers have never failed to stimulate interest in their special field. The latest lecture to be published (London: Oxford University Press. 1*s*. 6*d*. net), by Prof. H. Fleure on "Archæology and Folk-Tradition", deals with a matter of interest to both archæologist and folklorist, but perhaps at the present stage in archæological studies, more particularly to the former. The illustration, or perhaps illumination, of conclusions derived from archæological data by reference to tradition and legend may become an alluring, but somewhat hazardous, exercise in ingenuity. Prof. Fleure's suggested relation of "The Twilight of the Gods" to a period of climatic deterioration and racial unrest in bronze age Europe is suggestive, but at the same time by its very restraint inculcates caution in those who have not his wide knowledge of the archæological aspects of ancillary sciences such as meteorology, botany, and geography, which is essential for a synthesis such as he essays. Turning more specifically to Britain and the relation of British and Irish archæology to Celtic tradition, his interpretation, for example, of Irish ethnic tradition shows by precept and example how at each stage the argument must adhere rigidly to ascertained fact. Yet notwithstanding his caution, Prof. Fleure feels able to place some reliance on the traditional Spanish connexion of early Irish peoples and incidentally to offer an enlightening suggestion as to the possible origin of the obscure Tuatha de Danann.

Submarine Telephone Cables at Carrier Frequencies

IN ordinary telephony the sound waves falling on the microphone vary the pressure on the carbon granules through which a current is flowing. The resistance of the circuit thus varies, and so the current varies with the sound wave and in the receiver produces sound waves exactly similar to the original waves. In radio-telephony, in place of the current in the connecting wires, we have a high-frequency current emitted from the transmitter. This is varied (modulated) by the sound waves. These modulated waves falling on a suitable receiver reproduce waves similar to the original sound waves. Better results are obtained by using conducting wires, and in particular submarine cables. The cost of the cable in this case makes it necessary that it should carry pairs of wires providing several channels of communication. The disadvantage of this type of cable is the great difficulty of laying and maintaining it in deep water. For deep sea work a single core cable is used provided with a copper sheath under the armouring to carry the return current. In 1920 the serious single-channel limitation of this type of cable was overcome by the use of carrier wave high frequencies. This enabled telephone cables to be laid and operated between Key West (Florida) and Havana, a distance of 103 nautical miles. In a paper read to the Institution of Electrical Engineers on February 23, Dr. E. W. Smith discusses the electrical requirements for this type of transmission. He also summarises the most recent advances in materials and methods of construction and indicates probable future developments.

A Modern Granary

WHAT is described as the largest granary in South America, and in equipment, probably the most complete in the world, is described in *Engineering* for February 10 and 24 and March 10. The granary has recently been erected by the Buenos Aires Great Southern Railway at the port of Bahia Blanca, Argentina, at a cost of about £1,000,000. The plant consists of an unloading station for the discharge of grain from the railway wagons, a ferroconcrete granary of 80,000 tons capacity, a loading jetty and shipping galleries. For the transport of the grain there are no fewer than 120 conveyors having more than twelve miles of conveyor and elevator belting. The whole plant is driven electrically, current being supplied from a sub-station to some 240 electric motors of an aggregate horse power of about 10,000. Some idea of the capacity of the plant can be obtained from the statement that, while grain can be unloaded continuously at the rate of 1,000 tons an hour, on the outgoing side six ocean-going ships can each be loaded simultaneously at the same rate. Each year Great Britain imports about 1,000,000 tons of wheat from the Argentine, and it is a matter for satisfaction that the main contract for the buildings, plant and equipment of this notable granary amounting to about £800,000 has been carried out by Messrs. Henry Simon Ltd., of Manchester, at which place the machinery and equipment were assembled before shipment to South America.

Aluminium in Food-Stuffs

ATTENTION has been directed of late to the effects of, and possibility of poisoning from, aluminium derived from food-containers and cooking utensils. In view of the importance of the subject, the Mellon Institute of Industrial Research, Pittsburg, Pennsylvania, has instituted a critical search of the scientific literature relating to the chemistry and pharmacology of aluminium, and has now published "A Select Annotated Bibliography on the Hygienic Aspects of Aluminium and Aluminium Utensils", giving the scope, with critical notes, of the papers consulted (Bibliographic Series, Bull. No. 3). Dr. Beal, assistant director of Mellon Institute, contributes an introduction in which he concludes that aluminium is not a poisonous metal and does not give rise to any disease, that aluminium utensils are very resistant to corrosion by food-stuffs cooked therein, and that aluminium does not accelerate the destruction of vitamin or other food accessory substances during cooking.

Announcements

THE Right Hon. Lord Stonehaven has accepted nomination as president of the Institution of Naval Architects in succession to Admiral of the Fleet, Lord Wester Wemyss. The election of the new president will take place at the opening meeting to be held at the Royal Society of Arts on April 5.

DR. J. T. DUNN has been elected president of the Society of Chemical Industry for 1933–34, in succession to Dr. R. H. Pickard. Dr. Dunn was appointed headmaster of Gateshead School in 1886, and then head of the Plymouth Technical School in 1894. Later he became the first principal of the Northern Polytechnic, Holloway. He is now the public analyst of Northumberland, and in 1930–32 was president of the Society of Public Analysts.

THE gold medal of the Institution of Mining and Metallurgy has been awarded to Sir John Cadman, in recognition of his work in the advancement of technical education and the development of the mineral industries; and of his distinguished public services. The following awards have also been made: Consolidated Gold Fields of South Africa, Ltd., gold medal to Mr. C. A. Banks for a paper on "Air-Transportation of Gold Dredges in New Guinea"; Consolidated Gold Fields of South Africa, Ltd., premium of forty guineas conjointly to Mr. J. L. Francis and Mr. J. C. Allan for their paper on "Driving a Mines Drainage Tunnel in North Wales"; William Frecheville student's prize of ten guineas to Mr. G. J. Williams for a paper on "The Genesis of the Perrunal—La Zarza Pyritic Orebody, Spain".

AT the annual general meeting of the Geological Society of London held on February 17, the following officers were elected for the ensuing year: *President*, Sir Thomas Holland; *Vice-Presidents*, Prof. E. J. Garwood, Mr. J. F. N. Green, Mr. W. Campbell Smith, and Prof. W. W. Watts; *Secretaries*, Prof. W. T. Gordon and Prof. P. G. H. Boswell; *Foreign Secretary*, Sir Arthur Smith Woodward; *Treasurer*, Mr. F. N. Ashcroft.

UNDER the terms of the Thomas Gray Memorial Trust, the Royal Society of Arts is offering a prize of £100 for an improvement in connexion with the science or practice of navigation, invented in 1932 or 1933; also a prize of £100 for an essay on fire at sea. Further particulars can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

PROF. B. W. HOLMAN, honorary general secretary of the Association of Scientific Workers, 70 Victoria Street, London, S.W.1, informs us that the Association is engaged in compiling a handbook of "Extra-University Research in Pure and Applied Science", in which it is proposed to give data concerning commercial, endowed, and private laboratories not included in the "Universities Yearbook". It is not intended to include laboratories and other institutions devoted solely to testing materials and products, collecting data and other work not of a developmental and original character. Firms and others who are engaged in research are invited to communicate with the Association.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in mathematics and science as applied to the building industry at the Northern Polytechnic, Holloway, London, N.7—The Clerk (March 31). An assistant to the City Analyst under the Leeds Corporation—The Medical Officer of Health, 12, Market Buildings, Vicar Lane, Leeds, 1 (April 3). A woman lecturer in mathematics and elementary science at the Municipal Training College, Cottingham Road, Hull—The Principal (April 5). A demonstrator in physiology and dietetics at King's College of Household and Social Science (University of London), Campden Hill Road, W.8—The Secretary (April 13). An engineer-manager for the States of Guernsey Electricity Department—The President, Appointments Board, Royal Court, Guernsey (April 15). A senior assistant in the Nautical Almanac Office—The Secretary, Civil Service Commission, Burlington Gardens, W.1 (April 20). A professor of pathology at the University of Bristol—The Secretary and Registrar (April 20). A lecturer in civil engineering at the University of Leeds—The Registrar (April 22). A professor of mental and moral philosophy at the University of Otago, Dunedin, New Zealand—The High Commissioner for New Zealand, 415, Strand, W.C.2.

ERRATUM.—In NATURE of March 18, p. 385, col. 1, line 26, for "*Odonatra zibethica*" read "*Ondatra zibethica*".

Nuclear Energy Levels

It is a plausible hypothesis that the forces acting on a particle inside the nucleus are comparatively weak in the internal region and increase rapidly to the boundary of the nucleus, the potential distribution being represented by a hole with more or less flat bottom and rather steep walls[1]. If we approximate this model by a rectangular hole with infinitely high walls, the energy levels of a moving particle will be determined by the roots of Bessel functions and can be easily calculated. For the real model, however, this theoretical level system will be deformed owing to the fact that the walls are neither quite steep nor infinitely high, producing compression of the upper part of the level system.

The best nucleus for testing this hypothesis is that of radium C′, for which a lot of experimental evidence is available. For this nucleus we have the measurements by Rutherford[2] of long range α-particles (nine groups) giving us approximate positions of nuclear levels. The investigations of Ellis[3] give for a number of γ-lines (nine lines) their absolute intensities and, what is most important, the values of internal conversion coefficients enabling us, as has been shown by Taylor and Mott[4], to tell the dipole transitions from quadrupole transitions.

These data are sufficient to construct the level system of the radium C′ nucleus, the main part of which is represented in Fig. 1, together with the theoretical one.

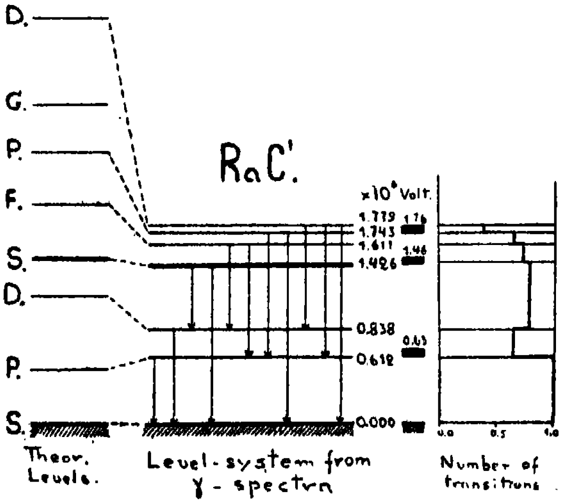

FIG. 1.

We see immediately that not every level corresponds to a long range α-group; this is, however, to be expected, as the probability of α-disintegration from a level with large j is comparatively small, due to the additional barrier of centrifugal forces (for equal energies the probability for an α-particle escaping from *P*-, *D*-, *F*-, *G*-levels will be respectively 1·3, 4, 16 and 105 times less than for the *S*-level). The observed transitions are given in the accompanying table.

CONSTRUCTED		OBSERVED		CONSTRUCTED		OBSERVED.	
$h\nu \times 10^{-6}$ volt	Δj	$h\nu \times 10^{-6}$ volt	Δj	$h\nu \times 10^{-6}$ volt	Δj	$h\nu \times 10^{-6}$ volt	Δj
0·588	2	0·589	..	1·131	0	1·130	0 ; 2
0·612	1	0·612	1	1·167	1	1·168	..
0·773	1	0·773	1	1·426	0→0	1·426	0→0
0·838	2	0·839	..	1·743	1	1·744	..
0·941	0	0·941	0 ; 2	1·779	2	1·778	0 ; 2
0·999	2	1·000	..				

From twenty-one mathematically possible transitions, eleven are actually found and, as can be seen from the table, have appropriate energies and obey the exclusion principle. From the remaining ten lines, two are not to be expected corresponding to $F \rightarrow S$-transitions, four fall in a spectral region not yet investigated and four are not observed, possibly due to comparatively small intensity. It is also of interest to construct an excitation diagram, building up the sums of the intensities for all lines crossing a given level interval. From this diagram we see that there must be a γ-line 0·226 × 10⁶ volt with absolute intensity about 0·2 which at present is not known.

The similarity of theoretical and real level systems proves the correctness of our picture of the potential inside the nucleus, and the deviations between these systems must permit us to calculate the real potential distribution.

Atomic Moments of Ferromagnetics

No satisfactory explanation has hitherto been given of the values found for the magnetic moment per atom in ferromagnetics, as deduced from the saturation magnetisation at low temperatures. These values for the three ferromagnetic elements are as follows:

Fe	Co	Ni	
11·0	c 8·6	3·0	Weiss magnetons
2·22	c 1·7	0·606	Bohr units

Now it is known from the experiments on the gyromagnetic effect that the g value for the carriers, at least at room temperature, is close to 2, while the form of the magnetisation temperature curves approximates closely to that for carriers for which $j = \frac{1}{2}$; the magnetisation may thus be attributed almost entirely to electron spin, any direct orbital moment effect, except possibly at higher temperatures, being comparatively small. A magnetic moment corresponding to an integral number of Bohr units per atom might therefore be expected.

To account for the non-integral values, two suggestions have been made (apart from those in which the reality of the Weiss magneton is accepted). In one of these (Stoner, 1926) the ferromagnetic is regarded as an equilibrium distribution of neutral atoms, ions and free electrons, the free electrons having no resultant moment, and the atoms and ions making contributions corresponding to their spin moments. In another (Wolf, 1931) a mixture of atoms in different possible spectroscopic states is postulated (for example, for nickel, ^3F and ^1D states, corresponding to moments of 2 and 0). To both of these suggestions there are a number of fairly obvious objections.

The essential fact which has to be explained is that the moment per atom in the aggregate is less than, though a considerable fraction of, the spin moment of the free atom in its normal state (2, 3 and 4 for nickel, cobalt and iron). It is suggested here that a satisfactory interpretation may be obtained by fusing the justifiable assumption of a positive interaction integral, the essential basis of the Heisenberg theory of ferromagnetism, with the treatment of the metallic state as developed by Bloch, Peierls, Brillouin, Wilson and others. The tendency to parallel setting of electron spins will be opposed by the tendency of the electrons to occupy the lowest 'cells' in the energy band or bands associated with the 'unpaired' electrons in the unperturbed atoms. Thus in nickel ($d^8s^2\ ^3F$) four cells are contributed to the aggregate by each atom, and two electrons.

The cells may be regarded as being in pairs corresponding to the two spin orientations for each momentum range. With normal interaction, the pairs of cells, from the lowest upwards, will be occupied by electrons with oppositely directed spin; but when the interaction integral is positive, there will be a number of uncompensated parallel spins. The equilibrium state will be that in which increase in the number of unpaired parallel spins, at the expense of the paired, corresponds to an increase in kinetic energy greater than the decrease in energy due to the interaction. The equilibrium is similar to that considered in the Pauli treatment of the constant paramagnetism of an electron gas, except that the tendency to parallel alignment is due to the interaction instead of to the external field. Numerically, the requirements are that the width of the energy band should be considerably less than kT_0 and greater than $k\theta$, where T_0 is the temperature corresponding to the zero point energy of the idealised free electron gas, of the order 10^4, and θ is the Curie temperature of the order 10^3. This width is compatible with the general theoretical indications.

The above treatment appears to lead also to a straightforward interpretation, in simpler cases, of the changes of atomic moment due to substitution of foreign elements in ferromagnetics, shown by Sadron's results for an extensive series of alloys, and to shed light on some of the obscure energetic characteristics of ferromagnetics. It is hoped that a more detailed account will be published shortly.

Range of Radiation from Samarium

In NATURE of December 3 we announced the discovery of radiation of α-ray type emitted by samarium. Recently we have determined the range of this radiation. The apparatus used, to which Prof. H. Geiger had kindly directed our attention, consisted of a perforated Geiger-Müller tube, surrounded by a cylindrical brass tube, the inside of which was coated with samarium oxide. The whole system could be evacuated, and the pressure could be varied until no more α-particles reached the counter. From the air pressure and the distance between the samarium oxide layer and the counter, the range of the particles could be determined. The value for the range of the samarium radiation in air at atmospheric pressure was found to be $1{\cdot}1_3$ cm. at 15° C. The reliability of the method was checked by determining the range of the α-rays of radium F and a value of 3·90 cm. was found. Making use of the known relation between range and velocity of α-particles, we can conclude that particles having the velocity of $1{\cdot}05 \times 10^9$ cm. sec. ^{1} are emitted by samarium. That samarium emits α-particles and not H-particles could be proved by comparing the magnitude of the electrometric deflections obtained when counting the number of α-particles emitted by samarium, and also the magnitude of the deflections which polonium radiation produced, when the range of the particles was cut down to $1{\cdot}1_3$ cms.

The calculation of the period of samarium from the range of radiation by means of the Geiger-Nuttall relation when making use of Gamow's formula requires the knowledge of the size of the samarium nucleus. When we assume the radius of the latter to be 6×10^{-13} cm., we obtain 10^{15} years, while to a radius of 8×10^{-13} cm., a half period of 10^{12} corresponds. The period of samarium may be determined by counting the number of α-particles emitted by a known amount of this element. We find, that 1 gm. of samarium emits 75 α-particles a second. From this it follows that the half period of samarium is $1{\cdot}2 \times 10^{12}$ years. If the activity is not due to the main isotope of samarium, but to a minor isotopic constituent, then the above figure has to be divided by the value of the concentration of the radioactive isotope. By comparing the period calculated by means of the Geiger-Nuttall relation, when making use of Gamow's formula, and the period obtained by counting the number of α-particles emitted, we can calculate the amount of the concentration of the radioactive isotope of samarium. Although the value given by Gamow's formula varies within large limits, it still permits us to conclude that the activity of samarium cannot be due to an isotopic constituent present only in small amounts.

It may be of interest to note that Prof. Joly[1] has directed attention to the pleochroic haloes produced by an unknown α-radiation of short range. In biotite of Japan, Iimori and Yoshimura[2] discovered haloes produced by α-rays having a range in air of 1·2 and 2·1 cm. It is possible that the first-mentioned halo is due to the action of the samarium radiation.

Simultaneously with our first investigation on the radioactivity of samarium, we experimented with other rare earth elements, with the exception of numbers 61 and 69, and found several of the preparations tested to be radioactive. Lanthanum and neodymium especially have shown pronounced activity. The character of the radiation observed suggested, however, that the activity is due to the presence of known radioactive elements, and in fact we were successful, by using the usual reactions of radiochemistry, in removing the activity observed. The only member of the radioactive disintegration series which cannot be removed by simple methods is the rare earth element actinium. The disintegration of actinium is, however, a 'rayless' one.

In a recent note, Libby and Latimer[3] announced the discovery of the radioactivity of lanthanum and neodymium, and stated that the activity of the latter element is nearly as intense as that of samarium; while that of lanthanum was found by them to be about three times more active than samarium. We have, therefore, to conclude that this activity is not a property of the elements themselves, but belongs to the radioactive impurities present, a possibility mentioned by the above writers.

A New British Record of *Orthopodomyia pulchripalpis*, Rondani (Diptera, Culicidæ)

ON March 8 we collected a number of mosquito larvæ from a rain-filled cavity in a local elm tree, and found them to be the second, third and fourth instars of the arboreal mosquito *Orthopodomyia pulchripalpis*, Rondani. So far as we are aware, this species has never been collected in the adult stage; its eggs have never been obtained; and records of its larvæ are few and far between.

The British localities in which tree-holes containing larvæ of *Orthopodomyia pulchripalpis* have so far been recorded are as follows:—Epping Forest, Essex (A. Macdonald, 1919, and H. Main, 1919): Kensington Gardens and Buckingham Palace Gardens, London (F. W. Edwards, 1926): Burnham Beeches, Bucks (P. A. Buxton, 1928): Cambridge (D. Keilin, 1929, and T. T. Macan, 1931): Ripley, Surrey (M. E. MacGregor, 1930): and Hardwick, Cambs (T. T. Macan, 1932).

In the present instance, the cavity containing the larvæ is a natural rot-hole; its entrance, which faces north-east, is about three feet from the ground. On the day following our discovery of the larvæ we scraped some vegetable matter from the walls of the cavity, and on examining this in our laboratory we found within it a few eggs, and a number of egg-shells, which are undoubtedly those of *O. pulchripalpis*. Both in structure and in surface markings these eggs appear to correspond exactly with a published illustration of the egg of the North American species *Orthopodomyia signifer*, Coquillet (formerly *Bancroftia signifer*, Coquillet)[1]. According to Dr. F. W. Edwards, *O. signifer* is structurally allied to *O. pulchripalpis*, but differs from it by having scattered white scales on the wings[2]. It seems probable to us that not only the adults of these two species but also their eggs may likewise be differentiated by coloration; for the eggs of *O. signifer* are said to be black[3], whereas the eggs that we have now obtained are light brown. Presumably, therefore, our local tree-hole has yielded the first known specimens of the egg of *O. pulchripalpis*.

An unusual feature exhibited by the egg-shells is the fact that the plane containing the opening made by the emerging larva is inclined at an angle of about 45° to the axis of the egg, instead of being at right angles thereto as in the genera *Aedes*, *Theobaldia* and *Culex*.

In published descriptions of the larva of *O. pulchripalpis*, attention has been directed to the remarkable enlargement of the thoracic portions of the two main tracheæ. We find that each main trachea has, in addition, two quite conspicuous dilatations lying within the fifth to seventh abdominal segments. This peculiarity (which appears to have been hitherto overlooked) is especially noticeable in the second and third instars. We venture to suggest that these tracheal dilatations may have some relation to the air-sacs which lie within the seventh abdominal segment of the larva in the case of *Chaoborus* and *Mochlonyx*.

Sporulation of *Helminthosporium avenæ* in Artificial Culture

IN 1923 an investigation was commenced on the fungus *Helminthosporium avenæ*. Recently an interesting observation was made and a note is now made of it.

Diversity of opinion exists as to the ease with which the various species of *Helminthosporium* produce spores in artificial culture. In view of conflicting statements, Turner and Millard[1] made a detailed study of a *Helminthosporium avenæ* culture. A wide range of media was used to embrace varying carbohydrate and nutrient contents, hydrogen ion concentration and sterilisation methods. No sporulation occurred on any of the cultures excepting on sterilised oat leaves, and then only sparsely.

I was myself unable to induce any marked sporulation until recently, when I inoculated two Petri dishes containing potato agar with mycelium from a non-sporing culture of *Helminthosporium avenæ*. Three days after the inoculation was made, the upper cover of the Petri dish was removed and a disc made from Sanalux glass was substituted. One half of the disc in both cases was painted over with Indian ink. Both cultures were then irradiated for ten minutes at a distance of one foot from a Hanovia quartz mercury-vapour home model alpine sun lamp, alternating current equipment, 200 volts. A subsequent irradiation was made for ten minutes, six days later. Seven days after this, the cultures were examined microscopically and it was noted that the mycelia on the irradiated halves were strongly pigmented and that very abundant sporulation had taken place: pigmentation was very slight on the non-irradiated halves and no sporulation had taken place.

Other experiments of a somewhat similar nature have shown that sporulation of *Helminthosporium avenæ* can be induced by irradiating with the light from a quartz mercury-vapour sun lamp; and also that sporulation will take place if non-sporing cultures are submitted, out of doors, to either strong diffuse light or sunlight. These experiments will be described elsewhere.

Origin of Spontaneous Mutations

SPONTANEOUS mutations are generally supposed to be induced by some unknown external agent. However, it may be expected that mutation is influenced also by certain intracellular processes which develop automatically and may be created or accelerated by artificial means (for example, by X-rays).

Seeking to secure some additional evidence, I decided to test the effect of *prolonged dormancy of seeds* upon the rate of chromosomal mutations. Resting seeds were selected as material for the following two principal reasons: first, because the alleged external slight influences are able to accumulate only in material that is not exchanged or propagated during the whole period of experiment; secondly, because the anabiotic state is distinguished by the preponderance of katabolic processes, which may be supposed to disturb in the course of time the energy balance within the cell; and it seemed to be not improbable that such a disturbance would ultimately increase the rate of mutation.

In the early spring of the past year, two mixed lots of aged seeds of *Crepis tectorum* L. were planted in the usual manner. One of them, culture No. 32.593, was collected in 1925 from plants each of which was individually examined cytologically during that summer. At that time the rate of spontaneous dislocations was about 0·1 per cent or *one per thousand* (M. Navashin, 1926). The second lot, culture No. 32.594, came from plants grown in 1926 largely from the same 1925 seed. Both lots germinated poorly and mostly produced abnormal and weak seedlings. Among them were recorded many albinos; the majority displayed various developmental abnormalities and died before forming the growing cone or soon after. The whole population strikingly resembled one obtained from soaked seed which had been treated by a heavy dosage of X-rays (for *C. tectorum* such an effect is obtained from dosages about 3000 r).

Some thirty plants survived until they reached the age when they could be transplanted into pots. Some of them afterwards died, so that full maturity was reached by only twenty-seven of them, twenty-two of culture No. 32.593 and only five of culture No. 32.594. When the plants were about two months old, root tip material was taken from them individually for cytological investigation. The plants were kept under observation and displayed various abnormalities during their further development; many of them showed great reduction of fertility. Seeds were collected from them individually for further investigation.

The study of the root tips performed in collaboration with Miss Gerassimova of this Institute disclosed an astounding fact: *the great majority of the plants* (more than eighty per cent) *were chromosomal mutants of one sort or another*. None of the mutant plants was uniformly altered in all its cells, but all were *chromosomal chimæras* composed of at least two kinds of tissues, one with the normal chromosome complement and the other or others containing reorganised chromosomes. The great majority of mutant roots were uniformly altered in all their cells but in two instances chimærical roots occurred. The alterations observed were translocations involving one, two or more chromosomes. One case could be interpreted as inversion.

The data obtained were unusual to such a degree that it might be supposed that some special conditions were responsible for the situation. In order to check this, several lots of aged seeds of *Crepis tectorum* (of different origin) were germinated. Some of them produced rootlets that contained no division figures, but one lot of 1927 gave good material. In spite of the high percentage of germination (it was as high as 39 per cent) no normal seedlings whatsoever were produced. In all rootlets from this seed the chromosomes were found to be in a state of profound disintegration, and disregarding rare normal cells, each individual cell displayed a chromosome complement *sui generis*. Grotesque fragmentations, translocations, chains of chromosomes, etc., were observed. Resting cells contained degenerating globules of chromatin scattered throughout the cytoplasm, and adventitious small nuclei were not infrequent. Of special interest was the occurrence of ring-chromosomes, a phenomenon which has been found only once in a single seedling raised from fresh seed among many thousand individuals studied (M.N., 1931). Again the picture strikingly resembled that observed in seedlings fixed very soon after X-raying.

Fuller discussion of the subject, together with additional evidence which is now being accumulated, will appear in the near future in a joint paper with Miss Gerassimova. The purpose of this preliminary note is to report the above facts, which undoubtedly deserve earnest consideration. If the phenomena reported above should prove to be of wide occurrence, the process of mutation, it is evident, should be considered from a new point of view, the theoretical and practical bearings of which are obvious.

An attempt to evaluate them at this stage of our knowledge may seem to be premature. One is safe, however, in concluding that, first, selective mortality had absolutely nothing to do with the enormous increase in the rate of mutation discovered (cf. De Vries, 1901; Heribert Nilsson, 1931); for, granting that as much as one per cent of spontaneous mutants existed in the fresh seed (which is ten times the actual value) the percentage of germination should obviously have been only one per cent to account for 100 per cent mutants, while in reality as much as 39 per cent of seed germinated. Secondly, the observed increase in the mutation rate cannot be attributed to accumulation of the direct effects of some external agency like radiation and the like; for the ratio of mutants was shown not to be proportional to the length of the period of 'rest', but, on the contrary, must have grown with an enormous and progressive velocity until after five years it was a thousand times as great as after one year. One is forced thereby to the conclusion that the main agency that caused spontaneous chromosomal mutations should be sought not outside but rather *inside* the cell. The same would probably also hold true for factor mutations.

Strepsinema Stage in Reduction

L. W. SHARP in his "Introduction to Cytology" (1st ed. 1921 and 2nd ed. 1926) and C. D. Darlington in "Recent Advances in Cytology" (1932) wrongly attribute the origination of the term 'strepsitene' to me. As a matter of fact, I never used this term, but suggested in 1899 the now generally used 'strepsinema'. I coined this word to describe the origin of the bivalent chromosomes of the heterotypic division first recorded by me in 1895 ("The Chromosomes of *Lilium longiflorum*", *Proc. R.I.A.*, 1895). The term 'strepsinema' is now often assigned to Grégoire owing, I believe, to an accidentally ambiguous expression of that writer, namely, "C'est le stade des noyaux *diplotènes* (Winiwarter, 00)—ou mieux noyaux *strepsitènes* ou *strepsinema* (Dixon, 00, Grégoire, 07), cette dernière expression rappelant les entrelacements caractéristiques de cette periode." ("Les cinèses de maturation dans les deux règnes" (second memoire). *La Cellule*, 26, 2, p. 239; 1910.) Grégoire, so far as I can discover, uses the term 'strepsinema' here for the first time.

With regard to the process of lateral approximation and twisting together of the separate chromosomes, now known to be homologous, and generally recognised as a normal stage of meiosis, I believe I was one of the first, if not the first, to observe and to describe it (*Proc. R.I.A.*, 1895 and "Notes from the Botanical School, T.C.D.", 1896). In this connexion I may again quote Grégoire: "La même année (1895) Dixon donne une interprétation toute différente. . . . Pour lui, les deux moitiés entrelacées qui constituent chaque chromosome, au moment où s'isole du peloton, ne sont pas le résultat d'une division longitudinale mais représentent deux tronçons du peloton qui, dès avant la segmentation transversale de ce dernier, se sont rapprochés et entrelacés. ("Les cinèses polliniques chez les Liliacées". *La Cellule*, 16, 2, p. 241; 1899.) Again p. 250: "Tous les auteurs, . . . , à part Dixon, décrivent cette division longitudinale. Dixon, au contraire, considère ces deux portions enroulées comme deux tronçons du peloton qui se seraient rapprochés et entrelacés." The view I put forward then is now generally accepted by cytologists, Grégoire included.

Variation Effect in Latitude, Correlatable with the Moon

IN NATURE of January 26, 1929, p. 127, a communication appeared dealing with the variation of latitude with the moon's position. Attention was directed to small variations of less than a tenth of a second of arc, determined from Gaithersburg observations, which appeared to be correlated with the hour angle and altitude of the moon. While in this preliminary note a marked dependence was exhibited of the magnitude of the latitude residuals upon the moon's position with respect to the observer at the time the zenith telescope observations were made, no direct attempt was made to separate the dependence of the moon's hour angle from that of the moon's declination.

Studies of the small variations in latitude (corrected for the 428-day term) have been systematically continued for other stations and years, yielding results of increasing interest.

Reductions have now been carried out for four of the international latitude stations for the years 1909-11, and the resultant residual variations in latitude grouped both by hour angle and declination of the moon. The accompanying graph (Fig. 1) shows the results for north declination, south declination, and for the time when the moon is near the equator between − 12° and + 12°.

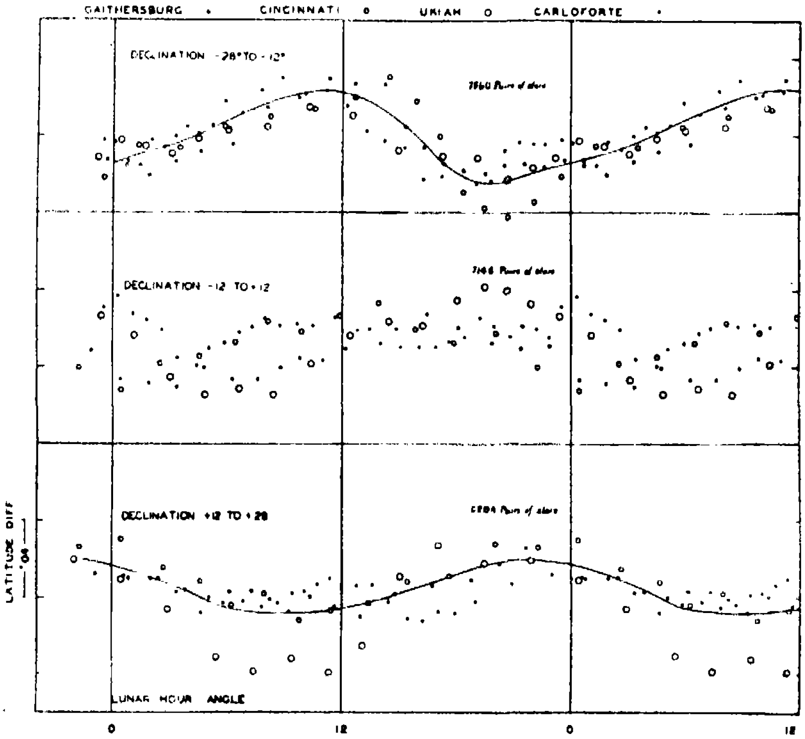

FIG. 1. Variation in latitude with the moon's hour angle and declination, 1909–11.

The resemblance of these curves to diurnal curves of equilibrium tides appears to give confirmatory evidence for an earth tide hypothesis. The inversion of phase for the change in the moon's declination is particularly significant in this respect.

The magnitude of the effect observed being 5–10 times greater than on the basis of our present knowledge of earth tides, suggests a possible mobility in the earth's crust at right angles to gravity. Some such hypothesis appears consistent with the results of tilt experiments, such as that of Michelson and Gale, and the displacements of the zenith here recorded in astronomical observations.

Structure of Triatomic Molecules

RECENT investigations of infra-red and Raman spectra of triatomic molecules have shown that molecules with an odd number of electrons, such as ClO_2 and NO_2, are similar in structure to the molecules SO_2 and CO_2, each with one more electron. This observation suggests that the triangular molecules have structures depending on the number of valence electrons binding the three atoms together, and that a scheme might be formulated for obtaining the structures of these molecules from the total number of available valence electrons.

A stable structure is first obtained with four electrons. Examples are H_2O and Cl_2O, molecules which have surprisingly similar structures: both have vertical angles near 90°, both satisfy only the central system of force constants, and both show a large resistance to deformation measured by H–H and Cl–Cl force constants of at least 5×10^5 dynes/cm.; further, the O–H and O–Cl force constants are each 7×10^5 dynes/cm., corresponding to single chemical bonds. In fact, these molecules are excellent examples of the Slater-Pauling molecule formed from a central atom with two *p*-electrons available for chemical bonds.

Proceeding one step further, a fifth electron is added and a new structure, that characteristic of SO_2, is obtained. ClO_2 has five available valence electrons, has a vertical angle near 120°, satisfies only the valence system of force constants, and resists deformation to a much less degree than either H_2O or Cl_2O, its tangential restoring force constant being $3 \cdot 5 \times 10^5$ dynes/cm. These structural properties are all repeated in SO_2, where the sixth electron completely fills the SO_2 type of proper function; this is the one feature distinguishing SO_2 from ClO_2, for the S–O force constant is approximately $9 \cdot 6 \times 10^5$ dynes/cm. whereas the Cl–O constant is only 7×10^5 dynes/cm., indicating that the sixth electron of SO_2 brings out the full bonding power of this type of proper function.

Next we seek a molecule with seven electrons; the typical example is NO_2. The addition of a seventh electron again requires formation of a new type of proper function, and this is characterised by a linear structure and small resistance to deformation, measured by a restoring couple constant of $5 \cdot 5 \times 10^{-12}$ dynes × cm. Addition of an eighth electron fills this linear type proper function, and raises the force constant of the chemical bond from 7×10^5 to 14×10^5 dynes/cm. Addition of the eighth electron does not otherwise affect the structure, the similarity of the restoring couple constants being a remarkable feature of the linear molecules NO_2, N_2O, CO_2, COS and CS_2. The C–S force constant is less than 14×10^5 dynes/cm., and may be accounted for by the increased separation of the nuclei.

The above scheme seems also applicable to triatomic radicals, and has been used to explain apparently inconsistent structures observed for the NO_2 group[1]. It also predicts an SO_2 structure for NOCl, and preliminary observations of the infra-red absorption spectrum appear to confirm this.

Hydroxyl Group in Ergosterol and Cholesterol

IN a recent issue of the *Annalen*[1] is a paper by Chuang in which the conversion of ergostane into *allo*-norcholanic acid, $C_{23}H_{38}O_2$, is described. This result is of considerable interest as it definitely establishes the identity of the nuclear skeletons of ergosterol, cholesterol, and the bile acids.

We have also been investigating the same question with the additional object of determining simultaneously whether the hydroxyl group in ergosterol is in the same position as in cholesterol which, as has been shown by Wieland and Dane[2], is almost certainly attached to carbon atom 3. With this object in view we have oxidised ergostanyl chloride, $C_{28}H_{49}Cl$, with chromic anhydride and have isolated a chloro-acid, m.p. 213°, analysis of which shows that it is a chloronorcholanic acid (found: C, 72·7; H, 10·0; Cl, 9·7 per cent; required for $C_{23}H_{37}O_2Cl$: C, 72·5; H, 9·7; Cl, 9·3 per cent). The formulation of this acid has obviously occurred by scission of the ergostanyl side-chain in the following manner:—

$$-\mathrm{CH(Me)CH_2CH_2\;CH(Me)CHMe_2} \quad\cdot\quad -\mathrm{CH(Me)CH_2COOH}$$

We are now engaged in degrading 3-chloro-*allo*-cholanic acid[3], $C_{24}H_{39}O_2Cl$, to the corresponding *nor*-acid in order to establish its identity or otherwise with our acid.

Constitution of Binary Alloys at Room Temperature

WHEN studying binary organic melts, it is customary to supplement the information obtained from the freezing point curve as to compound formation, solid solutions, etc., by examining the solubility isotherms. In this way, not only can it be decided whether or not the composition of a cold mixture is essentially the same as at its freezing point, but also a very fair approximation to the transition point of a compound can often be obtained by means of a solid model or projection diagram. For the purpose of the solubility measurements, the nature of the solvent is considered immaterial and solvation is not supposed to affect the range of stability of the compound.

This being the case, it occurred to me that a similar procedure might be applied with equally reliable results to binary alloys, using mercury as solvent, and plotting the results on a triangular co-ordinate diagram. Mr. H. D. Carter, working in my laboratory on the system mercury–manganese–tin, at 30°, is obtaining results which show that the procedure is feasible. Dilute tin amalgams are used as cathodes and manganese electro-deposited up to the appearance of solid phase. Perhaps the method may become of general application in metallurgical work.

Research Items

Archæological Discoveries in Uganda. Mr. E. J. Wayland figures and describes in *Man* for February relics of a culture at present unidentified from a site at the top of Luzira Hill, Port Bell, Uganda, of which the first indications were some remarkable heads of pottery figures found by natives in the course of building operations. A stratum of angular granite rubble, thought to be of middle Pleistocene or post-middle Pleistocene age, was found to contain artefacts belonging to two groups, one contemporaneous, the other derived. In a stratum of red earth above, were elongated continuations of the surface soil which were found to contain parts of pottery figures and a number of fragments of pottery vessels, all of which had been broken before being deposited in the pits. The pits were circular in horizontal section and showed no sign of any interment. On a hill-top a quarter of a mile away was found a shrine consisting of an earthenware pot containing rain water and a few coins and having a number of spears arranged point inward and other objects around it. Although the shrine is still or was until recently in use, the natives know nothing of its origin. Mr. Miles Burkitt, reporting on the stone artefacts from Luzira, considers the industry of great interest and compares it with that found by F. B. Macrae in the Kafue district of Northern Rhodesia, in a cave near Mumbwa. Mr. H. J. Braunholtz considers that the objects from the pits are older than those from the shrine. The pottery figures are remarkable for the head-dress and also for the conventional treatment of the body. In one figure the thighs are omitted. The figures are unique in African art. One small fragment of pottery has an ornament still in common use among the Baganda. These finds are probably only a few centuries old. Among the objects from the shrine the iron spear heads with tangs are peculiar for Uganda, while those with sockets and an eyelet between blade and socket are not a modern Baganda type and cannot be matched in the British Museum collections.

Ceremonial Exchange in Polynesia. Ceremonial exchanges of gifts, frequently mentioned by writers on Polynesia, apparently are quite meaningless from the economic point of view and indeed at times the gifts exchanged are of the same kind. A study of these ceremonial exchanges in Ontong Java, the Polynesian community in the Solomon Islands, by Dr. Ian Hogbin in *Oceania* (vol. 3, pt. 1) shows, however, that benefits are derived from these exchanges in various ways and that their uselessness is more apparent than real. In Ontong Java elaborate exchanges of food take place on various occasions. In betrothal, the most important, the father of the girl announces the fact to the head of his family group, through whom the announcement is conveyed to the headman. The headman immediately gives orders that the women of the group are to collect taro, which is brought to the house of the mother. The father and mother's brother in the meanwhile collect a number of coco-nuts, and a pudding is made, which when cooked is distributed among the women of the two groups concerned. The father of the boy also announces the betrothal to his headman, who decides how many coco-nuts are to be collected and gives orders for the men of the group to collect the nuts and also fish. The boy's mother's brother's group also collect nuts. The points to be noted in these exchanges are that, apart from any question of material gain, they bring the headman and the father prestige, and afford an outlet for pride and vanity without harm to other members of the community; they form a bond and impose a mutual obligation on two groups of the society as well as between individual members of the group; they emphasise the mutual relations of the head of the group and the individual member; and they also serve to stabilise marriage. They legalise the marriage, and establish the legitimacy of the children.

Restriction in Range of the Long-Billed Curlew. The long-billed curlew (*Numenius americanus*) once ranged over the entire width of the United States of America, where it frequented open prairie and the flat land about the marshes of the Great Salt Lake and similar localities. John W. Sugden (*Condor*, Jan. 1933, p. 3) points out that with the advance of civilisation and the cultivation of the prairies, the range of this curlew has been pushed westwards, so that the numbers now seen on the marshes and flats of Great Salt Lake represent rather a concentration in a restricted range than an increase in the number of birds. Actually there is a notable decrease in numbers. Even where cultivation is made impossible by the high alkalinity of the soil and poor drainage, nesting is disturbed by the increase of grazing stock of cattle and sheep. The latter especially destroy nests by trampling, so that the curlews are driven to less accessible and less suitable nesting territory. The area now occupied by the long-billed curlew is a limited portion of the Great Basin, but further restriction appears to be inevitable in view of the attempts to drain alkaline sloughs and the extension of sheep ranging.

Nephridia of *Amphioxus*. Prof. E. S. Goodrich (*Quart. J. Micro. Sci.*, 75, pt. 4, Feb. 1933) gives a new figure of the nephridia of *Branchiostoma* (*Amphioxus*) which shows that the number of blind branches bearing solenocytes is considerable and that the anterior canal attached to the primary gill-bar may be more than 0·3 mm. long. The paired nephridia of the allied genus *Asymmetron* (*A. lucayanum*), which were studied at the Biological Station, Bermuda, are built on the same plan as those of *Branchiostoma* but are smaller and simpler. From the pore, which opens into the atrium near the top of the secondary bar, the canal runs dorsally and expands into a triangular sac from the dorsal edge and outer surface of which the solenocytes chiefly arise. The solenocytes are rather larger than those of *Branchiostoma* and the tube of each, down which works a long flagellum, may reach a length of about 0·04 mm. The paired nephridia are retroperitoneal but the coelomic epithelium is interrupted and does not cover the solenocyte field so that coelomic fluid bathes the solenocyte tubes. The blood supply of the nephridium seems to be much less developed than in *Branchiostoma* and the conspicuous network of blood-capillaries described in the latter by Boveri is represented by only a few slender vessels in *Asymmetron*. In

Asymmetron as in *Branchiostoma*, Hatschek's unpaired nephridium is present, extends along the lateral wall of the left dorsal aorta and opens posteriorly and dorsally into the pharynx by a small pore just behind the velum. This nephridium reaches forwards slightly beyond Hatschek's pit and in the adult is nearly 2 mm. long. Along the course of the slender main canal are small dorsal and ventral solenocyte chambers into which penetrate branches of solenocytes from diverticula of the canal.

Late-Blight of Tomatoes. The fungus *Phytophthora infestans* is well-known in Great Britain for the damage it causes to the potato crop. In many parts of the United States it is also a serious menace to the extensive fields of tomatoes. Circular No. 169 of the United States Department of Agriculture ("Tomato Late-Blight Rot, a Serious Transit and Market Disease" by G. B. Ramsey and Alice A. Bailey, 10 pp.) describes the disease in detail. The symptoms are superficially like those of potato blight. Leaves are blackened and hang down from the stems, which in turn fall over. Wet seasons induce the abundant production of mycelium over the surface of affected parts. Fruits are also attacked, with the formation of watery brown places which may gradually extend all through the tomato. The fungus is capable of developing very quickly amongst fruit packed for transit, and large losses have been recorded at this time, though very little spread occurs from one fruit to another. Various treatments of freshly-picked fruit with water and with weak formaldehyde solution have failed to arrest development of the rot during transit, but spraying with Bordeaux mixture is a preventative when applied to the growing plants.

Differentiated Sills in Skye. The lower members of the great group of basic sills intrusive into the Jurassic strata of the coast of Northern Trotternish (Skye) form the subject of an investigation by Dr. F. Walker (*Trans. Roy. Soc. Edin.*, **57**, No. 7, 1933). Ophitic olivine-dolerite is the most widespread type of rock, but there is a noteworthy development of picrite in the thicker sills. Gravitational settling of olivine crystals can be clearly demonstrated in the well-known sill that forms the Kilt rock, and the process is thought to have occurred in other sills. In some examples, instead of a comparatively thin layer rich in olivine near the base, picrite occurs as the most abundant rock with relatively thin olivine-dolerite margins. It is shown that the lower members of the visible suite of sills contain considerable amounts of ultrabasic rock, and it is argued that differentiation must have been drastic in the feeding reservoirs, producing great accumulations of peridotite of which the Trotternish sills reveal samples. The recent suggestion that the non-porphyritic central magma type represents the parental magma of the Tertiary igneous rocks of this province is discussed. It is pointed out that it would seem to imply the production of a great preponderance of quartzose types over basic rocks of plateau magma type. Such preponderance is not indicated by the existing field evidence, which is thus at variance with the suggestion.

Soundings in the Scotia Sea. The waters of the Southern Ocean between Drake Strait and the South Sandwich Islands, west and east, and between the Falklands and South Georgia on the north and the South Shetlands and the South Orkneys on the south, are now known as the Scotia Sea in honour of the work of Bruce's expedition in the *Scotia* in that area. They would appear to be surrounded, except on the west, by a great hairpin ridge, partially submerged, which was originally known as the South Antillean Arc but is now called the Scotia Arc. Many thousands of soundings taken in this region by *Discovery II* and associated ships are recorded on charts published in "Discovery Reports", vol. 6. "Report on Soundings taken during the Discovery Investigations 1926–1932". By H. F. P. Herdman (Cambridge University Press, 15*s*.). Most of the soundings were taken by the echo methods, which admitted of seried rows of soundings where formerly the scattered observations of *Scotia* and *Antarctic* were almost the only data. Mr. Herdman discusses the probability of the Scotia Arc being a line of folding and shows that the weight of evidence, both oceanographical and geological, is in favour of a structural connexion between South America and Graham Land. Folded large-scale charts are provided in a separate case and coloured bathymetrical charts, which show earlier soundings also, are bound into the report.

Isotopes of the Radio Elements. The *Physical Review* for January 1 contains several papers describing applications of the Allison magneto-optical method to finding metallic isotopes. This method consists in observing the Faraday magneto-optical rotation produced by solutions of the metallic salts and measuring the lag between the application of the field and the appearance of the optical effect. The light from a spark is polarised and passed through cells over which are wound magnetising coils fed with high-frequency currents from the spark circuits. One of the cells contains the solution under investigation, and the other contains a comparison liquid. The coils produce opposite rotations and the occurrence of a characteristic time of lag is detected by a minimum in the light intensity as the optical path between the cells is changed. Even with very dilute solutions, it is claimed that the presence of molecules of a particular isotopic variety makes itself evident by the occurrence of a characteristic lag. In the papers under notice, the method is applied to lead (sixteen isotopes), bismuth (fourteen isotopes), radium (four isotopes), uranium, thorium and thallium (eight isotopes each). The abundance of the isotopes in the specimens was estimated from the minimum concentrations in which the characteristic lags could be observed. On the basis of the isotopic constitutions found for these elements, Edna R. Bishop constructs a table of the radioactive elements and their relations which is in good accord with the known facts of radioactivity.

Philips Sodium Lamp. A notable improvement in the efficiency of certain sources of monochromatic radiations has resulted from the recent development of the hot-cathode discharge tube. An interesting example of the new type of source is the Philips sodium lamp, a specimen of which has been submitted to us by Philips Industrial, 145 Charing Cross Road, London, W.C.2. The lamp consists of a small glass envelope containing a coiled filament, which constitutes the cathode, two other ring-shaped electrodes, and small quantities of inert gas and sodium. The lamp operates from A.C. mains, of voltages from 215 to 230, in association with a rectifier which provides heating current for the filament and the requisite low voltage for the glow discharge. The visible spectrum of the lamp immediately after starting is due chiefly to the inert gas, but the heat generated by the discharge vaporises some of the sodium, and the spectrum of sodium gradually supersedes that of the gas. Maximum brilliancy is attained within 10–15 minutes after starting the lamp, and the spectrum then consists entirely of sodium lines, the yellow *D* lines being by far the most intense. The other lines, situated in red, green and blue regions, can be removed, or reduced to very low intensity, by using a yellow gelatine filter or a potassium bichromate cell. The brightest portion of the source consists of a central cylinder about 2·5 cm. long and 2·5 cm. in diameter. A Dewar flask and a polished metal radiation shield are provided with the lamp for maintaining it at the appropriate operating temperature. The lamp is simple to operate, provides a highly intense and steady source of the *D* lines, and has many obvious laboratory applications, particularly in colorimetry, polarimetry and refractometry.

Detection of Traces of Carbon Monoxide in Air. The extremely poisonous character of carbon monoxide and its presence in the exhaust gases of motor-car engines render the easy detection of traces of this compound a necessity of modern life. The lowest concentration of carbon monoxide in air which will produce fatal results when breathed is said to be not greater than 0·1 per cent and has been computed by Hempel to be about 0·05 per cent. In the *Chemiker-Zeitung* of February 25, Dr. W. Ackermann of Breslau describes the results of comparative tests made with the two reagents which have hitherto been regarded as being most sensitive to carbon monoxide, namely, diluted ox-blood and palladous chloride. Hæmoglobin is said to absorb carbon monoxide about 130 times as readily as oxygen, but differentiation between the absorption spectra in the two cases is only possible after the addition of a reducing agent (ammonium sulphide), when the characteristic bands disappear unless carbon monoxide has been absorbed. On the other hand, the gas reduces palladous chloride very readily to the free metal and the colour and transparency of the reagent may be observed during the whole course of the experiment. Even when no deposit can be seen by the naked eye, its presence can sometimes be revealed by filtering the solution. The results are very striking. By passing 1 litre of air containing varying small amounts of carbon monoxide through the reagents for one hour, it was possible to detect 0·015 per cent of the gas by the palladous chloride method, as against 0·13 per cent by the hæmoglobin method.

Astronomical Topics

Geddes's Comet. This comet has now been observed for more than eight months, but is still a fairly easy object, and is likely to be followed for most of 1933, if not longer. *Astronomische Nachrichten*, No. 5934, contains a fine series of observations extending from June to December, made by J. Tretter at Cordoba Observatory (Argentine).

The comet is now in north declination 10°, and is observable for most of the night. Since its orbit is probably hyperbolic, it is important to keep it under observation. It was observed by M. Beyer at Hamburg on March 1. It was an oval nebulosity 2′ in diameter, the combined light being of mag. 9·7, and the nucleus of mag. 11·6. An ephemeris for the whole year is given in the Handbook of the British Astronomical Association for 1933; the error of the ephemeris does not exceed 2′ or 3′.

Variable Stars in the Globular Cluster M.53. It was the study of cluster-variables that led to the important law correlating period with absolute magnitude; this law permitted determinations of distance to be made in the case of objects beyond the range of all previous methods. Herr E. Grosse, of the Bergedorf Observatory, has made a study of the variables in Messier 53, in Coma Berenices (*Astr. Nach.*, 5901). Light curves are given for thirty-four variables. Most of these are of the characteristic cluster type, with rapid rise and slow decline, but a few of them conform more closely with regular sine curves.

The distance of the cluster is determined as 19,500 parsecs; Prof. Shapley had found 18,200 parsecs by rougher methods (diameter of cluster, total light, and magnitude of brightest stars). Grosse's value places the cluster 3,700 parsecs from the galactic plane. Its diameter was reckoned from the angular distance of the outer variables from the centre, and found to be 89 parsecs, about the same as Messier 3 and Messier 5. It is estimated that 7 per cent of the stars in M.53 are variable; in ω Centauri the percentage is 4, in M.3 it is 15.

Minor Planets. The volume of "Kleine Planeten" for 1933, just published by the Berlin Rechen-Institut, gives evidence of the zeal of many astronomers both in discovering new planets and in keeping the known ones sufficiently observed. The planets with permanent numbers now extend to 1,223, having increased by 40 during the year. Each year a list is given of planets for which observations are specially desired. 35 of the objects thus listed last year have been re-observed. Orbit elements are given for all the numbered planets. Dr. Witt gives a revised orbit of 433 Eros, which he discovered in 1898; the new elements, for 1925, Jan. 1·0 U. T. are: M 204·560°, ω 177·945°, Ω 303·710°, i 10·830°, Φ 12·879°, n 2,015·258″, a 1·4581. The interesting planet 944 Hidalgo, which travels out to Saturn's orbit, has been out of sight for ten years; it may possibly be seen by southern observers next September, its magnitude being 15·4.

The remarkable planet discovered by M. Delporte a year ago, which approaches the earth within ten million miles, has now the number 1,222, and the name Amor; an ephemeris is given for next October, but as its magnitude is 21, its recovery can scarcely be expected. The tenth Trojan planet, 1,208 Troilus, was in opposition on December 31, 1932, in north declination 55°, magnitude 15·2. Eros is in opposition on June 27 in south declination 36°, magnitude 11·1.

The New Compressed Air Wind Tunnel at the National Physical Laboratory

THE new compressed air tunnel for aeronautical research at the National Physical Laboratory, recently completed and now being brought into use, is the largest and most up-to-date of its kind, and the second one only in the world. A small tunnel on the same principle has been working in the United States for several years, and the British one has incorporated in it many new features found desirable during the use of this earlier type.

The theoretical basis of the new compressed air tunnel at the National Physical Laboratory is to be found in Rayleigh's law of dynamical similarity, upon which the validity of all model research in aerodynamics rests. This law may be written

$$R = \rho v^2 l^2 f(vl/\nu)$$

where R is any particular aerodynamic reaction, for example, the lift or the drag of a model aeroplane, v is the relative speed, ρ is the air density, l is a characteristic length of the model, ν is the coefficient of kinematic viscosity of the air, and $f(vl/\nu)$ represents some function of vl/ν which cannot be determined theoretically. The implication of this law in predicting full-scale characteristics from model tests is obvious. Thus if the model is tested at atmospheric pressure and temperature, the only way to be absolutely certain of predicting full-scale forces accurately is to test at the same value of the product vl.

A simpler approach to tests under these conditions, except in the matter of size, is seen in the very large wind tunnel, having a jet measuring 60 ft. × 30 ft., recently erected in the United States. Testing on such a large scale is very convenient for some purposes, but for most branches of research it is preferable to work with smaller models. In many cases the variation of the function $f(vl/\nu)$ with scale is not serious, so that tests in an ordinary atmospheric pressure wind tunnel of moderate size give all the accuracy required. Ample justification for ignoring changes in $f(vl/\nu)$ between tunnel and full-scale has now been provided by the agreement between full-scale flying measurements and model results obtained in such tunnels. But in some instances, notably the maximum lift coefficients of aerofoils, there may be a pronounced 'scale effect', that is, change in $f(vl/\nu)$ with scale or speed. It is here that Rayleigh's law provides a relatively simple solution, for the quantity ν varies inversely as the pressure, so that if the air is compressed to n atmospheres, the model scale by speed product can be reduced in the ratio $1/n$ without affecting the value of $f(vl/\nu)$. This principle is made use of in the new compressed air tunnel, in which the air can be compressed to 25 atmospheres. The maximum wind speed in the six-foot diameter jet is about 60 miles per hour, so that tests at full pressure on a 1/10 scale model simulate precisely the conditions of the full-scale aircraft flying at 150 miles per hour.

The working section in which models are tested is 6 ft. in diameter. The air flowing through this section returns through an annular space surrounding it, being circulated by a fan. This requires a diameter of 17 ft. for the containing shell, which is made of steel nearly 2½ in. thick. The shell was designed and made by Messrs. John Brown and Co. Ltd., of Sheffield, and consists of four rings, each rolled from a single ingot, and jointed together by circumferential straps fitting over slight flanges on the ends of the rings. The four rings together form a cylinder 17 ft. in internal diameter and 32 ft. long. The ends of this cylinder are each completed by two steel castings forming a hemisphere. At one end is a special labyrinth packing through which the fan shaft passes to the external driving motor, while the other end has a door for access to the tunnel. The internal air passages forming the wind tunnel itself were designed at the National Physical Laboratory by tests on a small model, modifications being made until the uniformity of the air flow was satisfactory. In the actual tunnel, the internal structure is built entirely in steel, light castings being used in the curved portions, and steel plates on suitable framing in the straight parts. A honeycomb is introduced at the point of lowest air speed to straighten the flow, and is immediately followed by a rapid contracting jet just before the working section is reached. This results in very steady and uniform distribution of speed across the working section. The air is circulated by a metal airscrew or fan driven by a 400 h.p. motor. Air is compressed into the shell by three 400 h.p. compressors housed in an adjoining room, and capable of charging the shell to the full pressure of 25 atmospheres in about ninety minutes.

An observer cannot work inside the tunnel at this high pressure, and the readings of the balances on which the models are suspended have to be recorded outside. This is done by an extremely interesting and unique electrical apparatus which can transmit the readings to any point as desired. The air forces to be measured are balanced by electromagnetic attractions between coils of wire, the current in which is controlled from outside. The current required for balance is measured and thus gives a direct indication of the air force acting on the model. Certain movements of the model are also made by electric motors controlled from outside the tunnel.

Selectivity and Radio Communication[*]

IT has long been a commonplace remark that one of the greatest problems in the technique of radio communication is the avoidance of the reception of undesired signals. Improvement and developments in methods of reception have made it comparatively easy to receive intelligible signals from almost any transmitting station under a variety of conditions, but these methods increased rather than reduced the difficulties of eliminating interference due to signals emanating from stations other than the one from which it is desired to receive. For telegraphic communication the difficulty has in the past been partially overcome by increasing the selectivity of the receiving circuits so far as stability would permit, but the use of shorter wave-lengths and of directive aerial systems has also contributed to the solution. With the inception of broadcasting and

[*] F. M. Colebrook: "A Theoretical and Experimental Investigation of High Selectivity Tone Corrected Receiving Circuits", Radio Research, Special Report No. 12. (London: H.M. Stationery Office, 1932.) 1*s*. 3*d*. net.

the rapid development of emitting stations in restricted geographical areas, the effects of radio interference have been brought home to a much wider public.

On a first inspection of the problem as applied to the reception of speech and music, as in telephony or broadcasting, it appeared that the relatively high selectivity of the telegraphic circuits could not be utilised on account of the distortion which would arise from the loss of the higher note frequencies in the audible range. Recent research has shown, however, first, that the problems of the reduction of interference are the same in all branches of radio communication; and secondly, that the correct application of existing knowledge on radio frequency circuit operation can be of considerable assistance in reducing the interference experienced in any conditions of radio reception.

On account of the importance of this subject, the Radio Research Board appointed a special committee, under the chairmanship of Prof. E. V. Appleton, to report on the properties of very highly selective radio receivers. On behalf of this committee, Mr. F. M. Colebrook carried out a theoretical and experimental investigation of the subject, and the results of this work, together with the committee's considered conclusions on the problems involved, are contained in a report recently published by the Department of Scientific and Industrial Research.

In the course of this investigation the general problem of the reception of modulated electrical oscillations in a circuit of known constants has been considered in a comprehensive manner. The research has been limited in the first place by the assumption of quasi-stationary conditions, and it is realised that the results of imposing transient conditions will need further consideration. Moreover, the investigation was specially directed to studying the behaviour of a circuit of high selectivity, that is, a tuned oscillatory circuit in which the current amplitude falls very rapidly as the frequency of the inducing electromotive force is displaced by comparatively small amounts from its resonant value. The practical application of this work consists in the use of such a high selectivity circuit as part of the apparatus employed for receiving modulated radio signals in the presence of similar signals at neighbouring radio frequencies which it is not desired to receive. The distortion already referred to which results from the gradual amplitude reduction with increasing modulation frequency may be corrected for by using one or more audio-frequency stages in which the amplification obtained increases with the frequency in the requisite manner.

In the case postulated, the desired signals may be assumed to consist of a carrier wave with associated side waves due to telephonic, telegraphic, or other modulation, and it is by the combination of the effects of these waves in the receiver in their correct phase relationships that reception takes place. Under the conditions stated above, the total interference can be classified into two groups. The first includes all interference which would exist even in the absence of the carrier wave of the wanted transmission. A familiar example of this is the reproduction in a broadcasting receiver tuned to a certain station of the programme of another station transmitting on a neighbouring frequency or wave-length. The second group comprises all interference which would disappear completely if the carrier wave of the wanted transmission were removed. The most important and familiar example of this type of interference is the steady heterodyne beat note resulting from interference between the carrier waves of the wanted and unwanted transmissions.

The results of the investigations of this case show that, by the use of a highly selective receiving circuit in combination with a suitable tone-corrected audio-frequency amplifier, interference of the first type can be reduced to almost any desired extent within certain practical limits of circuit and transmission frequency stability. In the case of interference of the second type, however, the position is totally different in that the magnitude of this interference is independent of circuit selectivity, the relative reduction of interference in the selective circuits being removed by the subsequent tone correction. On account of the presence of this second type of interference, the frequency difference between the carrier waves of the wanted and unwanted transmissions must be at least twice as great as the audio-frequency range it is required to cover in the modulation signals transmitted and received. The advantage to be gained by the reduction of the first type of interference is considerable, and it is likely that the principles, now well established, will attract considerable attention in the future of radio receiver design and practice. The principles apply equally to all classes of receiving apparatus, whether these are for broadcast reception, for telegraphic reception using Morse code signals, or for the reception of those modulation signals which are employed in television and picture telegraphy.

The Priestley and Pepys Commemorations

WHEN Priestley on April 8, 1794 left the shores of England to seek an asylum in the United States, he could little have thought that nearly a century and a half later his name would be on everybody's lips and that men of light and learning would gather together in many places to pay tribute to his memory. After fleeing from Birmingham in 1791 in fear of his life, he had reached London only to find himself shunned by many of his fellow members of the Royal Society, and as the French Revolution, for which he had at first had much sympathy, reached its climax, his position had become so unpleasant, if not hazardous, that he was driven to the conclusion that his removal would be of more service to the cause of truth than his longer stay in England.

Thus it came about that just a month before France saw her greatest man of science fall beneath the guillotine, England allowed one of her noblest sons to become a voluntary exile. To-day, however, the name of Priestley, like that of Lavoisier, is held in honour throughout the world and the celebrations which have recently taken place in London and elsewhere have done much to atone for the neglect shown him in his later years.

Of these celebrations the most important was that of March 15, when at Burlington House the president of the Royal Society, Sir Frederick Gowland Hopkins, held a reception to commemorate both the bicentenary of the birth of Joseph Priestley and the tercentenary of the birth of Samuel Pepys. Needless to say, the rooms in which Sir Frederick received the guests were not the apartments known to Priestley, for when in 1773 at the hands of Sir John Pringle he received the famous Copley medal, the Society was still housed in Crane Court, whence, seven years later, it removed to Somerset House. But no doubt Priestley would have found much with which he had once been familiar, for when he was admitted a fellow of the Society in 1766, the Society was more than a hundred years old, and among the exhibits open to the visitors on March 15 was the Charter Book signed by all fellows.

The most interesting exhibits at the Royal Society's reception were those relating to Priestley himself, gathered together from many sources. Among these were to be seen a letter in French intimating to Priestley that he had been nominated for the National Convention, an honour he wisely and firmly declined; the diploma and seal given to him by the Empress Catherine II of Russia and his Copley medal, presented with such graciousness by Sir John Pringle, who remarked that the Society awarded it to him "as a faithful and unfading testimony of their regard, and of the just sense they have of your merit, and of the persevering industry with which you have promoted the views, and thereby the honour of the Society". The diploma, seal and medal were recently bequeathed to the Society by one of Priestley's great-granddaughters and it was to a great-great-granddaughter, Mrs. Belloc Lowndes, that the Society was indebted for the loan of some of the other exhibits, including the letter referred to. Most of Priestley's books, manuscripts and apparatus were destroyed in the fire at Birmingham in July 1791. Another exhibit of great interest was a series of documents, hitherto unpublished, lent by Lord Lansdowne. Beside the Priestley exhibition, there was also a small collection of documents recalling Pepys's connexion with the Royal Society. During the evening Sir Harold Hartley gave an address on Priestley's work.

The Priestley bicentenary was also commemorated in the provinces and his association with Lancashire, Yorkshire and Warwickshire was recalled by articles in the *Manchester Guardian*, the *Leeds Mercury* and the *Birmingham Mail*. His connexion with Leeds was a very close one, for he was born at Fieldhead, close to the city, he attended Batley Grammar School, and in 1767 became the minister of Mill Hill Unitarian Chapel. On March 11, therefore, the Old Boys' Association of Batley Grammar School had a Priestley commemoration dinner at the Hotel Metropole, Leeds, and on the following day a special service was held in Mill Hill Chapel, which was attended by the Lord Mayor of Leeds, Alderman R. H. Blackburn, and members of the Leeds Philosophical Society. During the course of his sermon, the Rev. W. L. Schroeder, referring to Priestley's statue in the city square, said it was symbolic of Priestley's endeavour to bring the light of truth within the reach of all; adding that though most people thought of Priestley as a man of science, it was more important that he was a minister, all of whose activities were devoted to the glory of God and the happiness of mankind.

The Chemical Society will commemorate the Priestley bicentenary by a special meeting in its rooms at Burlington House, London, W.1, on April 6 at 8 p.m., when papers will be read by Prof. A. N. Meldrum, Sir Philip Hartog and Sir Harold Hartley.

University and Educational Intelligence

CAMBRIDGE.—Mr. W. J. Courtauld has provided the sum of £6,000 for the repair of glasshouses in the Botanic Garden.

Sir Charles S. Sherrington will deliver the Rede lecture at 5 P.M. on May 24. The subject will be "Mechanism and the Brain".

Prof. B. L. Van der Waerden will deliver the Rouse Ball foundation lecture on April 24 at noon. The subject will be "The Aims of Modern Algebra".

It has been recommended that Dr. U. R. Evans be appointed assistant director of research in metallurgy for the period during which he holds the Royal Society Armourers and Braziers' research fellowship in metallurgy; and that the post of assistant in experimental research in crystallography be established in the Department of Mineralogy and Petrology for F. I. G. Rawlins, of Trinity College.

C. C. Hurst, of Trinity College, and A. F. Hallimond, of Pembroke College, have been approved for the degree of Sc.D.

WALES.—The Council has accepted with regret the resignation of Dr. S. Dickinson, assistant lecturer in botany at the University College of South Wales and Monmouthshire, Cardiff, on his appointment as research assistant in mycology in the Department of Agriculture in the University of Cambridge.

WITH the twenty-first volume, recently published, the series of "Methods and Problems of Medical Education" issued by the Rockefeller Foundation of New York is for the time being brought to a close. This series was begun in 1924 and has comprised volumes of articles devoted to descriptions of teaching facilities and methods in the field of medical education. The present volume deals with nursing education and schools of nursing, and several institutions in the United States and Canada, Peiping and Bangkok, are described and illustrated. Articles on nursing education in England, Denmark, Finland, France and Hungary are also included.

BILINGUALISM and the employment as a medium of instruction and examination of a language other than the mother tongue of the student give rise to problems of educational administration in many parts of the British Empire and especially in India. Some of these problems are dealt with in a report recently published by the Government of India, Central Publications Branch, Calcutta (pp. 48, price As. 10 or 1*s*.) on the use of the mother-tongue in the matriculation examination of the University of Bombay. It appears that since 1925, matriculation candidates have been permitted to write either in English or in their mother-tongues their answers in history and in Indian classical languages, and the proportion of candidates who have availed themselves of this option to write their history answers in their mother-tongue has steadily increased from one fifth in 1926 to two thirds in 1931, although more than half of the students in the high schools in the Presidency are receiving instruction in English. An analysis of matriculation results goes to show that those who answered the history papers in their mother tongue as a rule gained higher marks than the others but did badly in English.

Calendar of Nature Topics

The 'Borrowed Days'. The Blackthorn Winter

March 29–31.—The last three days of March are said to be marked by unusually fierce winds, sleet, snow and frost. The legend, widely spread in various forms, is that March borrowed them from April to extend his sway. In a Spanish version quoted by Inwards, a shepherd promised March a lamb if he would temper his winds, but after gaining his point refused to pay over the lamb; in revenge March borrowed three days from April, in which fiercer winds than ever blew. The 'blackthorn winter' comes about the same time; it is said that there are generally some warm days at the end of March or beginning of April which bring the blackthorn into bloom, after which comes a cold period called the 'blackthorn winter'.

Depletion of Nutrient Salts in the Sea

In NATURE of February 25 reference was made in this Calendar to the annual spring outburst of planktonic diatoms in the sea. The growing plants consume nutrient salts—phosphates, nitrogen compounds, silicate, and carbon dioxide—and their removal from solution in the water as the plants increase in abundance may be surprisingly rapid. In 1931, between March 23 and April 22, 81 per cent of the nitrate and 70 per cent of the silicate was removed from the sea in the vicinity of Plymouth. Indeed, chemical analysis of the sea-water affords the readiest means of following the diatom outburst. The annual production of phytoplankton in the whole of the English Channel has been calculated to be at least 115 million metric tons, of which the greater part is formed in a few weeks in the spring. In the Barents Sea the outburst occurs about a month later than in the English Channel. In low latitudes, sunlight is always sufficient to permit of plant growth and nutrient salts do not therefore accumulate sufficiently for a big spring outburst to take place. Where, however, upwelling currents bring nutrient salts from the rich reserves in the ocean depths—as off Cape Verde and along the coast of California—a rich plankton may flourish at other seasons.

Spring Outburst of Spawning in Mollusca

Although a few common British gastropods spawn in autumn and winter—notably *Patella*, *Littorina littorea*, *Buccinum*, *Purpura*, *Trivia arctica*, and certain of the Rissoidæ, by far the larger number breed in spring and summer. In March the marine plankton quite suddenly becomes full of all kinds of gastropod veligers, and eggs are laid in any suitable place. Some time during this month we should find the eggs of *Littorina obtusata* and *Lacuna vincta* laid on the seaweeds between tide marks, and just below low water the egg capsules of *Nassarius* on weeds and Bryozoa, and of turrids on anything available. The nests of *Lamellaria* and of *Trivia monacha* in compound ascidians on the shore are also to be found about this time. In March, too, *Aporrhais pes-pelicani* begins to lay its eggs singly in the sandy mud of the sea floor. These are only a few instances of the general rush of molluscs to begin breeding in this month. Many of them continue to lay all through the spring and summer as well.

In the plankton, an inshore haul in March is usually full of the free-swimming larvæ of *Nassarius*, *Rissoa*, and *Lacuna*. The beautiful little Echinospira larva of *Lamellaria* and *Trivia* with their accessory shells also abound. All these feed upon the microscopic plants and animals to be found at this time in the surface layers of the sea, especially diatoms. There can be no doubt, in fact, that larval molluscs devour a very large part of the annual spring crop of diatoms in our waters.

"The Sea-Blue Bird of March"

Although the kingfisher is traditionally associated with the Halcyon Days, the seven days before and after the winter solstice, a more natural association is with the present month. It is now that it is specially noticeable by the river, partly because March sunshine picks out its brilliance against sombre backgrounds, partly because its movements are still unobscured by foliage, and mainly because the mated birds are busy hunting for nesting sites. It was on March 19 that Mr. R. B. Rivière first noticed the digging of the nest-tunnel of the pair, the habits of which he has recently described (*British Birds*, Feb. 1933, p. 262). The tunnel was completed on March 21, both birds apparently sharing in the excavation, but it was then neglected until March 27, and was finally deserted for an old nesting hole nearby. Egg-laying began on April 27; the parents, sharing incubation, began to sit on May 3 or 4, and on May 23 the hen carried the first food to the nest for the young. The period of incubation therefore occupied about 20 days, and the development of the young, from hatching to flying, 27 days. It was noted that as the young grew they were fed upon larger and larger fish, and these were invariably presented to them head first, the position in which the adults themselves always swallowed their prey. Surely Shelley must have been taking full advantage of the poet's handicap when he described how "I saw two azure halcyons . . . thinning one bright bunch of amber berries."

Opening of the Nesting Season

Each season one species of bird or another, generally the starling, house-sparrow or wood-pigeon, endeavours to break the record of early nesting, but generally speaking, March may be said to mark the opening of the nesting season in Britain. Before the end of the month it might be possible to find the nests of about twenty-six different species, and thereafter with the influx of summer migrants the numbers steadily rise, so that almost a hundred kinds of nests may be found in April. In the latter half of May, nesting activity reaches its climax, and although June also is a favoured month, the numbers begin to show a decline which progresses rapidly through July and brings the normal nesting season to an end in August, when a persistent group of perhaps seven or eight species carry on the last of their series of clutches.

Distribution of Manure

At least one and a quarter million tons of chemical manures are used in Great Britain every year, and by far the greater part of this is applied between mid March and mid May. The actual method of distribution is a matter of some importance, for uneven spreading may involve the crop in local starvation or poisoning as the case may be. Moreover, these irregularities when once established are not readily rectified. Much thought has been given to the construction of manure drills, and comprehensive tests have been conducted from time to time to test the various machines in respect of uniformity of distribution over the surface of the ground. In practice, the drill is usually followed by some cultivating implement the function of which is to mix the fertiliser with the soil so that depth distribution as well as surface distribution is in question.

Until recently, the degree of mixing attained by the various classes of implements was only a matter of conjecture, but an ingenious method has now been devised in Germany to render the particles of manure in the soil directly visible, thus enabling depth distribution studies to be undertaken in soil samples carefully removed from the field. The fertiliser is treated with anthracene before sowing, and after distribution and cultivation the samples are examined in ultra-violet light. By this means it has been found that the newer rotary cultivation gives a more uniform distribution than either the surface working implements or the plough. The extent to which these differences of location of the fertiliser affect the crop has not yet been extensively investigated, although on general grounds thorough incorporation would seem to be desirable, particularly with relatively insoluble manures.

Societies and Academies

London

Royal Society, March 9. J. H. Awbery and E. Griffiths: The heats of combustion of carbon monoxide in oxygen and of nitrous oxide in carbon monoxide at constant pressure. The heat of combustion of carbon monoxide in oxygen is 282,730 joules per mole at 20° C., correct to within 3 parts in 1,000. The heat of reaction when nitrous oxide burns in carbon monoxide is 364,340 joules per mole, correct to 2 or 3 parts in 1,000. From these two results, the heat of formation of nitrogen dioxide at constant atmospheric pressure and at a temperature of 20° C. is found to be 81,610 joules, that is, 19·50 cal.$_{15^\circ}$ per mole. This quantity is determined as the difference between two heats of combustion, which were carried out with the same apparatus used in the same manner for both sets of experiments. R. W. Fenning and F. T. Cotton: A bomb calorimeter determination of the heats of formation of nitrous oxide and carbon dioxide. By means of a bomb calorimeter the heats of reaction of oxygen and nitrous oxide in carbon monoxide and hydrogen respectively were measured. Thus, by difference, two values were obtained for the heat of formation of nitrous oxide. A value for the heat of formation of carbon dioxide from carbon monoxide and oxygen was also obtained. Since the combustion of oxygen in hydrogen formed the calibration process, all the values given are based on the acceptance of 68,320 gm. cal.$_{15^\circ}$ as the heat of formation of water (liquid) at constant pressure and at 25° C. On this basis, the heats of formation of nitrous oxide and carbon dioxide at a constant pressure of 1 atmosphere and at 20° C. were found to be—19·74 ± 0·07 kcal.$_{15^\circ}$, or 82,600 ± 290 international joules, and $67{\cdot}65_5 \pm 0{\cdot}03_5$ kcal.$_{15^\circ}$, or 283,090 ± 150 international joules respectively. A. H. Hughes and E. K. Rideal: On the rate of oxidation of monolayers of unsaturated fatty acids. The method of surface potentials has been employed to study chemical reactions occurring in a unimolecular film; the reactions examined being the oxidation by acidified potassium permanganate of long chain unsaturated aliphatic acids such as oleic acid. The reaction velocity depends on the accessibility of the double bond to the oxidising agent, and decreases markedly on compression of the film. Reaction velocity has been studied as influenced by the position of the double bond in relation to the polar carboxyl headgroup. Autoxidation in a unimolecular film has been observed for the elaeostearic acids, and the effect of hydroquinone as an antioxygen to this reaction has been examined.

Edinburgh

Royal Society, Feb. 6. F. A. E. Crew: A case of non-disjunction in the fowl. An exceptional gold cock, *ex* Light Sussex × Rhode Island Red, when mated to Light Sussex females produced 66 silver males, 2 silver females, 48 gold females and 1 gold male. Cytological examination detected trisomic diploid silver males amongst the progeny. The number of the small autosomes is variable, and the small Y could not be distinguished from these. It was not possible, therefore, to identify any other cytologically exceptional types. The genetical and cytological evidence warrants the conclusion that this exceptional cock is an instance of secondary non-disjunction of the sex-chromosomes. A. C. Stephen: Studies on the Scottish marine fauna—the natural faunistic divisions of the North Sea as shown by the quantitative distribution of the Mollusca. By the changes in the density and identity of the dominant species of molluscs, especially lamellibranchs, the North Sea within the 100 fathom line may be divided into four zones: (*a*) littoral zone extending to about 2 fathoms; (*b*) coastal zone extending to about 20 fathoms in Scottish waters but covering the southern North Sea with the 30 fathom line which lies to the north of the Dogger Bank; (*c*) offshore zone covering much of the remaining area; (*d*) Thyasira and Foraminifera zone occupying a small area in the north-eastern North Sea near the Norwegian Deep. Communities are regarded as special cases of zoning. A. Crichton Mitchell: Diurnal incidence of disturbance in the terrestrial magnetic field. By using as a measure of activity, $(Xr_X + Yr_Y + Zr_Z)/1{,}000$, where X, Y, Z are the force components and r_X, etc., are hourly ranges, it is shown from the records of Eskdalemuir Observatory for 1914–25, that diurnal distributions of activity in the field can be represented as a mixture of two different types. One of these is due to ionisation in an upper layer of the atmosphere, 213 km. high, and is produced by the action of ultra-violet light from the sun. It varies in its time of on-set with the varying time of sunrise at that height. The second is due to ionisation in the Heaviside layer, about 90 km. high, produced by corpuscular streams from the sun. It has a maximum at 10.30 p.m. and does not alter in phase with the season of the year. The height of the upper ionised layer was found to have a seasonal variation of type very similar to that of the amplitude in the second term of the harmonic series representing the diurnal variation of pressure. Louis Herrman and Lancelot Hogben: The intellectual resemblance of twins. The intelligence-quotients of four hundred twin pairs have been determined. The separation of like sex pairs into identical and fraternal classes has been made with the assistance of Stocks's finger-print diagnosis. The correlation coefficients corrected for attenuation by Spearman's formula were found to be: identical pairs, 0·86 ± 0·04; fraternal twins of like sex, 0·48 ± 0·08; fraternal twins of unlike sex, 0·53 ± 0·06. The mean differences for fraternal and identical pairs are in the ratio 2 : 1 in accordance with previous observations by Holzinger and by Tallman. The contribution of genetic differences to the distribution of intelligence within the family is discussed. Sib correlations in this investigation were *found to be significantly lower (0·37) than correlations* for fraternal twins. Other data also point to the significance of birth rank in determining differences of *I.Q.* Ch. Koller and Thelma Townson: Spermatogenesis in *Drosophila obscura*, Fallen. (1) The cytological basis of suppression of crossing-over. Homologous chromosomes associate in pairs during metaphase and anaphase of the spermatogonial division, and this association sometimes results in a fusion of their ends. They enter into prophase of the first meiotic division with their ends already associated. The *X* and *Y* associate at one end, and this association persists through prophase of the first meiotic division.

Paris

Academy of Sciences, Feb. 6 (*C.R.*, 196, 377–447). The president announced the death of M. Mesnager. J. Costantin: Objections to the mycorrhizal theory. Discussion of objections raised to the author's theory of the cause of resistance of sugar-cane to disease produced by altitude. Georges Durand: The stability of rows of vortices. Y. Laure: The combustion pressures in closed vessels of air–benzene mixtures. An account of experiments on the explosion pressures developed in a sphere and three cylinders of different ratios of height to diameter. For a fixed ratio of surface to volume the results differ according to the bomb employed: *varying the ratio of surface* to volume by the introduction of thin metal sheets is unsatisfactory since the results depend on the position of the sheets. V. Dolejšek and Mlle. E. Filčakova: The *M* series of tantalum obtained by means of an ionic tube. Robert Ferber: A purely photographic method for the orthogonal projection on a horizontal plane of topographical plans. R. Titéica: Vibrational spectra and the structure of the molecules of methyl and ethyl alcohols. Measurements of the infra-red spectra of the vapours. P. Le Roux: Study of the pleochroism of Iceland spar in the infra-red spectrum. For the specimens of Iceland spar studied, in the infra-red region between 2·2 μ and 4·4 μ, as soon as the absorption becomes large, it is impossible to admit that it is independent of the direction of propagation of the light. Q. Majorana: The action of a *periodic light beam on metallic sheets*. The conclusions given in an earlier note on the same subject, while in part confirmed; require modification. Mme. Irène Curie and F. Joliot: The conditions of emission of neutrons by the action of α-particles on the light elements. The elements studied were beryllium, boron, lithium, aluminium and fluorine. The nuclei Al^{27} and F^{19} undergo two different modes of transmutation, one with the emission of protons, the other with emission of neutrons. Such a case has not hitherto been observed, since for boron the neutron emission is attributed to B^{11} and that of protons to B^{10}. R. Lespieau and Mlle. B. Gredy: The study of some α-ethylene oxides. A comparison of the Raman spectra for ethylene oxide and some of its derivatives. The characteristic frequency of the ethylene oxide nucleus is about 1,250, which is common to all the spectra. A. Lalande: The freezing points of binary mixtures of ethyl alcohol and ethyl ether. The curve showing the freezing point as a function of the composition has two branches: one corresponds to the separation of solid alcohol, the other probably to a separation of pure ether. No stable molecular complex is indicated. *H. Muraour and G. Aunis: The laws of combustion* of colloidal powders. A. Girard and G. Chaudron: The dissociation of cubic ferric oxide. In microcrystalline mixtures of artificial or natural oxides of iron, X-ray analysis is powerless to detect the presence of the cubic variety: the dissociation curves give more information. P. Demougin: The solubility of gun-cottons. G. Rumeau: Optical antipodes and crystallisation velocities. The non-existence of racemic substances in the liquid state. Georges Fournier and Marcel Guillot: The relation between the absorption of β-rays by organic compounds and the molecular structure of the latter. The results of experiments described show that the deviation between the observed and calculated coefficients of absorption are in direct relation with the chemical constitution of the molecule, especially with the nature of the linkages between the atoms of *carbon B. Bogitch: The reduction and oxidation* of the manganese silicates. Mlle. Caillère: A fibrous sepiolite from Madagascar. Dinca Samuiacas: The influence of the X-rays on the formation of the crystalline germ. C. L. Alexanian: The establishment of the map of anomalies of the vertical component of the earth's magnetic field in the plain of Alsace. M. Chadefaud: The existence of an oriented infra-visible structure of the cytoplasm in Algæ. A. Maige: The physico-chemical heterogeneity of plasts. Louis Gallien: The histological transformations correlative with the sexual cycle in *Polystomum integerrimum*. Mme. Françoise Bloch: Fecondation and maturation of the egg in *Diogenes pugilator*. Etienne Wolff: The topography of first rudiments of the liver, from the study of omphalocephalous fowls. Maurice Lecamp: Transplantations of rudiments of the posterior limbs in *Alytes obstetricans*. *Th. Kofman: The diffusion by the human skin of* visible and ultra-violet radiations. A. Dognon: The action of monochromatic X-rays of varying wavelength on the egg of *Ascaris*. M. Mascré and R. Paris: The action of formol on emulsin and invertin. H. Burgevin: The fixation of atmospheric nitrogen by the bacteria of the Leguminoseæ. A. J. Kluyver and J. C. Hoogerheide: The influence of oxygen on alcoholic fermentation.

The Severn Barrage Scheme*

THE long awaited report on the practicability of the proposal for the establishment of a great hydro-electric power generating installation near the mouth of the Severn, to be actuated by the tidal waters of the estuary in conjunction with an impounding dam, generally known as the Severn Barrage Scheme, has, at last, appeared. Interest in the matter may be expected to revive with the publication of the report and especially when the Cabinet pronounces its decision thereon, but much of the keen attention which was excited by the original promulgation of the project has died down during recent years. It was put forward in 1920, in unusually glowing terms, by the Ministry of Transport, and advocated as a means of opening up a "vista little short of a revolution in the industrial life of the West and Midlands of England" and of bringing "within the reach of all classes of the community the blessings of light, purity and power". In political and labour circles, with an enthusiasm, which neglected, perhaps, to take into account the limitations and delays inherent in the realisation of constructional undertakings of great magnitude, it was hailed as a heaven-sent inspiration for the immediate absorption of a large bulk of unemployed labour. These highly coloured expectations have given place to a more sober and reflective outlook.

In the intervening period, the scheme has been receiving careful and painstaking investigation by a Committee of the Economic Advisory Council, of which Lieut.-Col. J. T. C. Moore-Brabazon, M.P., is chairman. The technical features of the project not unnaturally presented a number of complex problems, some of them of quite a novel character. It is claimed in the report that this is the first tidal power scheme of any magnitude to be investigated in any part of the world in which a solution of the problems has been indicated. No reliable judgment, therefore, could be formed on the feasibility of the project, until the whole of the physical conditions and the constructional details had been examined from a strictly scientific and economic point of view. The results of the execution of the work were bound to be too far-reaching and drastic in their repercussions on a variety of important interests for it to be treated otherwise than with the most serious attention. The professional men associated with the deliberations and conclusions of the Committee were Sir John Snell, Sir Basil Mott, Sir H. P. Douglas, Prof. A. H. Gibson, and Mr. T. Shirley Hawkins: these names are a sufficient guarantee that this duty has been faithfully and consistently performed. Theoretical calculations have been supplemented by the operation of models and experimental apparatus of a very elaborate character in an endeavour to arrive at a true picture of the results.

---

* Economic Advisory Council. Severn Barrage Committee Report. Pp. 28. (London: H.M. Stationery Office, 1933.) 6*d*. net.

As the outcome of its labours, the Committee has issued a carefully considered verdict on the technical side of the undertaking. Following the lines of the interim report of 1929, the Committee finds that there are no insuperable difficulties, geological or otherwise, in the way of the construction of a barrage, and it indicates a suitable site for the structure at the English Stones, on a line approximately parallel to the existing Severn Tunnel. It states, however, that a power station at the barrage, dependent entirely on tidal action, would not produce electrical energy at a cost which could compete economically with energy generated at selected coal-fired stations. On the other hand, with an auxiliary scheme of water storage, which the Committee has examined for a suggested site in the Wye Valley and finds to be quite practicable, it is considered possible to produce a supply of electrical energy, somewhat less, it is true, than that obtainable from the barrage alone, but still of considerable proportions and adequate to meet one thirteenth of the total likely requirements of the whole country in 1941 (estimated at 21,000 million units) at a cost which would be only two-thirds of that due to generation at equivalent coal-fired stations. This would mean the substantial saving of between a million and a million and a quarter pounds per annum.

The capital sum required for the realisation of this outstanding enterprise is of correspondingly colossal dimensions, remarkable even in these days of Brobdingnagian finance. With auxiliary features—roads, railways and harbour facilities—it is estimated to run to over fifty millions sterling. Moreover, the scheme cannot be conjured into existence by the stroke of a magician's wand: it will take fifteen years of steady and persistent effort, during which it is estimated that the number of men employed on construction and manufacture will increase gradually from 2,000 in the first year to 12,000 in the tenth, thereafter rising rapidly to a maximum of 27,800 in the thirteenth year. The Committee does not anticipate that the work could be commenced before 1937, consequently no effective operation would be realised before 1942. In cases of all major engineering works, a great deal depends on the accuracy of the forecasts of time and outlay. In the present instance, the premises for these forecasts are attended by rather greater uncertainty than usual, and it is of interest to note that the allowance for contingencies in the expenditure is 12½ per cent. Moreover, the rate of interest for loans has been calculated at 4 per cent, although the present market rate for Government guaranteed loans is about 3½ per cent. The Committee wisely emphasises the risk of unforeseen difficulties and the danger that the estimates may prove inadequate.

Not the least important consideration in the investigation, apart from the main object of the scheme—the generation of cheap supplies of electricity—has been the probable physical effect of the construction of a solid barrier across the Severn estuary and the consequent interference with the established regimen of the tidal region and the upland water discharge—an interference which may bring about changes affecting in greater or less degree the navigable approaches to the docks at Avonmouth and the port of Bristol in the seaward portion and the transportation conditions to and from the port of Gloucester above the barrage. This aspect of the matter has been carefully investigated by Prof. A. H. Gibson with the aid of a large scale tidal model in an extended series of experiments, from which it would appear "that a barrage would not injuriously affect navigation *below* the barrage", while, "even without dredging, a barrage would not seriously affect navigation *above* the barrage at any time of the tide, and would appreciably improve it at low water". How far this pronouncement, founded as it is on relatively minute movements of silt-laden salt water in a model on a distorted scale, will go to alleviate or dispel the apprehensions entertained by the authorities of the ports of Bristol and Gloucester, it is difficult to say, but they will undoubtedly require to be convinced in no uncertain way that their important trade interests are not likely to be prejudicially affected by the proposed undertaking. A strong point in support of the general reliability of the model experiments is that they have satisfactorily reproduced the main conditions in the estuary at the present time after a period of operation representing seventy-eight years of past history.

Another matter of public concern is the question of floods, which, in the upper reaches of the Severn, are often of a serious character. Fears have been expressed that control of these visitations would be rendered more difficult by the existence of a barrage. The report states that, on the contrary, the model experiments show that a barrage would provide a means of reducing inundations in times of flood. Prof. Gibson's reports on the operation of the model do not accompany the Committee's Report; they will be awaited with interest for the additional light they will throw on the methods by which these important conclusions have been reached.

Sanitation has not been overlooked, and it is satisfactory to have the assurance that the barrage would not seriously affect the question of sewage disposal. With reference to the auxiliary features of the scheme (docks, roads, railways and other transport facilities), it is pointed out that, in combination with a supply of cheap electricity, they may lead to the establishment of new industrial centres, which, as potential sources of trade, offer the prospect of financial return on the outlay.

The foregoing is a necessarily brief review of the principal conclusions arrived at by the Barrage Committee as a result of prolonged and praiseworthy researches. After pronouncing a favourable opinion on the practicability of the scheme from a technical point of view which is sure to command general professional assent, the Committee is careful with judicial impartiality to direct attention to other considerations of a non-technical character "such as the social, economic and industrial reactions of the scheme upon the district", which lay outside the terms of reference and therefore did not concern the Committee in drawing up its report. These considerations are admittedly of the highest importance and will have to be carefully taken into account before the country can commit itself to an outlay of the magnitude suggested. The prospect of a great augmentation of power at favourable rates of generation is undoubtedly attractive, especially to a community like our own, which is dependent on its industrial output for its livelihood and prosperity, and faced nowadays with the fierce competition of other nationalities. None the less, it is essential to exercise due circumspection before the country embarks on an enterprise which, for good or evil, will leave a permanent impression on its surface and an indelible record in its history.

B. C.

International Economics

The Means to Prosperity. By John Maynard Keynes. Pp. 37. (London: Macmillan and Co., Ltd., 1933.) 1*s.* net.

NOTABLE in themselves, and doubly notable for their appearance in the *Times*, Mr. Keynes's recent articles on "The Means to Prosperity" have now been rounded off by a short introduction and conclusion and republished. Mr. Keynes's thesis in essence is the familiar argument that schemes of capital development or, as he terms it, loan-expenditure, are the only available means for creating employment, stimulating demand, raising prices, and so extricating the world from the present depression. Since loan-expenditure by public and semi-public bodies for housing, transport and similar capital works normally absorbs a large proportion of the activity of the capital goods industries, and since private business will not enlarge its demand for capital goods until *after* prices and turnover have increased and profits have become reasonably assured, Mr. Keynes urges that the loan-expenditure which the present situation demands should be embarked on by Government, first through reversal of the contractionist policy which has prevailed for the past year and a half, and then through the launching of new schemes of needed development.

Such schemes, Mr. Keynes argues, by reducing outlay on the dole and increasing the national income and therefore the yield of taxation, will benefit the Exchequer and stimulate industry generally. Since, however, no country by single-handed efforts can increase the volume of employment sufficiently, and since contradictory policies in various countries would cancel the advantages of expansionist efforts, in order to bring about world recovery fresh loan-expenditure must be undertaken simultaneously in all important countries by international agreement. The difficulties and fears of central banks, and the shortage, outside France and the United States, of internationally acceptable means of payment, would however prevent the expansion of credit which must accompany reviving trade. In order to solve this problem, Mr. Keynes advocates the issue by an international authority of gold notes to a total of 5,000,000,000 dollars which, allocated to each country in appropriate proportions against corresponding gold bonds, would give elbow-room for the growth of credit and the revival of activity.

The framing of an agreed scheme along these lines Mr. Keynes regards as the chief task of the World Economic Conference and the only hope of trade revival; and provided that such agreement can be reached, and that the essential subsidiary measures and steps are taken to end exchange restrictions, lower tariff barriers and generally encourage trade, Mr. Keynes would be prepared to see concurrently a qualified *de facto* return to a controlled gold standard. Mr. Keynes is always on the side of the angels, and once again he offers the inspiriting example of clear scientific thinking in a bemused world. Certain details of his argument—notably the probable cost of providing employment for an unemployed man—may perhaps be questioned. The general soundness of his thesis commands wide assent alike in official and technical circles and amongst the general public; and though before recovery can be finally assured, there must be an international political settlement which will abate fear and restore confidence, a vigorous expansionist policy would itself contribute to a political settlement as well as hasten the revival which must come soon if industrial civilisation is not to crash finally and disintegrate.

War and Post-War Explosives

Explosives: their History, Manufacture, Properties and Tests. By Arthur Marshall. Second edition. Vol. 3. Pp. xiv+286. (London: J. and A. Churchill, 1932.) 42*s*.

MARSHALL'S "Explosives" was first published in 1915 at a time when interest in the subject had been stimulated by the necessity for the production of service explosives on a scale unprecedented in the history of the world. Republished in a second edition in 1917, the addition of new matter, particularly on nitro-aromatic compounds, necessitated its expansion to two volumes. The treatment of the subject suffered from the unavoidable restrictions imposed by the necessity of maintaining secrecy concerning the composition, manufacture, and applications of many of those materials in use as service explosives, which precluded the publication of information obtained during the early years of the War.

In the years immediately following the War, many publications relating to the production of explosives and to investigations of their properties were released from Government and other sources. Foremost among these are "Technical Records of Explosives Supply", compiled by W. McNab, and a number of papers from the Research Department, Woolwich, under the ægis of Sir Robert Robertson. The same was true of Germany, France, and the United States, all publishing information hitherto withheld for military reasons.

The new volume under review embodies a large proportion of this information, also the results of work carried out in the intervening years. It must be regarded as a supplementary volume to the first two, and not as complete in itself. The subject matter is arranged in twelve parts and two appendixes corresponding to those in the first two volumes, the paragraphs having marginal references to the relevant pages in that edition.

The whole work forms a valuable summary of the manufacture and properties of explosives, and has been kept within due bounds by the omission of information concerning those raw materials of the industry, details of which are to be found in other works of reference. It is suggested that the three volumes could with advantage be combined in a single volume printed on a thinner and tougher paper, the supplementary paragraphs being inserted in their appropriate places. Possibly the author and publisher will consider this when a new edition becomes necessary.

The first two parts of the new volume deal with the early development of shell and black powder, the latter formerly of prime importance as a service explosive, but now of minor application, its place having been taken by the modern smokeless propellants and high explosives. In the industrial field, it still survives in various forms as a blasting explosive for use in quarrying and mining operations. It is interesting to note that picric acid in the form of its potassium salt was first prepared by Glauber early in the seventeenth century, but the application of the acid to military purposes was delayed until late in the nineteenth century, when it was adopted in the British service as a high explosive shell-filling under the name of 'lyddite'.

Parts 3–7 are concerned with the chemistry and manufacture of modern types of explosive and of their raw materials, based for the most part on the nitric esters of cellulose and glycerine, and on aromatic nitro-compounds. The manufacture of the acids necessary for the nitration processes has undergone great development since 1914; in Great Britain a rapid expansion took place in the production of 'oleum' by the various modifications of the contact process, and in the manufacture of nitric acid by the traditional method using Chile saltpetre as raw material. In Germany the supplies of sulphur, pyrites, and Chile saltpetre were restricted, and intensive development of alternative raw materials and processes was effected; large quantities of sulphuric acid were made by the decomposition of sulphates such as gypsum and kieserite; nitric acid was produced by the oxidation of ammonia synthesised by the Haber and cyanamide processes. Only in post-War years were synthetic methods of production developed in Great Britain at Billingham. For the concentration of weak sulphuric acid, a product of nitration operations, the Gaillard tower proved to be the most efficient type of plant for handling large and continuous tonnage, but for the intermittent and smaller demands of normal production, the Kessler concentrator still holds its own.

The chemistry of cellulose has undergone considerable revision in the light of X-ray spectrography, and of the work of Haworth and others. The supply of cotton cellulose for the manufacture of 'nitro-cotton' presented no insuperable problem to the Allies during the War, but in the case of the Central Powers early recourse was had to wood as an alternative raw material. Some difficulty was experienced in both cases in obtaining a cellulose of suitable chemical and physical properties, but this was largely overcome by the adoption of controlled methods of preparation in place of the cruder methods formerly used. The nitration and stabilisation processes for the most part followed well-tried methods, which are still in use in slightly modified form. Nitric esters derived from other carbohydrates have been prepared and examined, but on grounds of high cost or poor stability have not displaced those of cellulose and glycerine to any great extent.

In the case of glycerine, an interesting application was made of Pasteur's fermentation process, many thousands of tons of glycerine being produced. Some progress has been made in recent years in the continuous nitration of glycerine, in which greater safety is attained owing to the much smaller quantities of explosive present in the nitrator at any one time as compared with the usual batch-nitration method.

Large quantities of glycol were nitrated during the War in order to conserve glycerine, but only latterly has this become an economic process owing to the fall in the price of glycol. 'Nitroglycol' is now largely used as an ingredient of 'non-freezing' explosives.

Previous to the War, the usual filling for high explosive shell was picric acid, but soon after the outbreak of war it was seen that the supply available was quite inadequate. This led to the adoption of T.N.T. and of mixtures of T.N.T. with ammonium nitrate (amatols) as the main types of filling, and called for the development of new methods of large-scale manufacture. The results of preliminary experiments at the Research Department, Woolwich, were embodied in the design of large factories at Queensferry and elsewhere, the production of T.N.T. finally rising to nearly 100,000 tons per annum. Many improvements were introduced, particularly in the method of purifying the crude explosive. The manufacture of picric acid was also continued and expanded, increased efficiency being obtained by the adoption of continuous methods.

In Germany other nitro-compounds such as hexanitro-diphenylamine and picryl sulphide were used in addition to T.N.T. and picric acid.

The enormous propellant requirements of the army led in Great Britain to the introduction of a new type of cordite designated R.D.B. (Research Department 'B') in which acetone was replaced by a mixture of ether and alcohol as a solvent in manufacture, the raw material for the latter being more readily available than acetone. More recently, propellants have been made in which the use of a volatile solvent is dispensed with, thus eliminating the dangerous and slow process of drying from manufacture.

Part 8 deals with blasting explosives, which are increasingly numerous. During the War large use was made of chlorates and perchlorates to take the place of nitrates. The latter in the form of sodium and ammonium salts are largely used in this type of explosive.

The evolution of methods for the determination of the physical and chemical properties of explosives has made great strides during and since the War; noteworthy among these are the application of Sir J. J. Thomson's piezo-electric method to the measurement of the pressure of explosion, of Hopkinson's pressure bar to the measurement of the pressure and violence of detonation, and of the condenser discharge method to the measurement of the velocity of detonation. On the chemical side, much has been done in devising tests for the detection and measurement of instability, notably the gas evolution test of Farmer, and a number of tests for the measurement of the acidity of the products of instability by the use of electrometric methods, or of suitable indicators.

The final section of the book deals with revised methods for the examination of raw and finished materials, and thermochemical data additional to those in vol. 2 are given in an appendix.

The book is well printed, well indexed, contains few errors or misprints, and can be confidently recommended to all those who are interested in explosives, professionally or otherwise.

R. C. Gale.

The Rayon Industry

Cellulose Acetate: its Manufacture and Applications. By A. G. Lipscomb. Pp. xii + 304. (London: Ernest Benn, Ltd., 1933.) 21*s.* net.

It is difficult to keep closely in touch with the development in those branches of industry which become successful and popular at a particular time, because the technical discoveries are either obscured in the form of patents or explained in special journals which are seen only by the few. Hence it is not until some expert considers it advisable to disclose his knowledge in book form that a general perspective of the subject can be obtained by the outsider. This is particularly true of the cellulose acetate industry and its applications in the form of rayon and elsewhere, and Mr. Lipscomb's effort is sure of a receptive public. It is written from a dual point of view, aiming both at giving a complete account of the manufacture of cellulose acetate from its raw materials, including a full account of the up-to-date methods of making these, and also at summarising the very considerable patent literature: a list of these patents is included in a special index.

The rayon industry has not yet made up its mind whether it should properly belong to the textile or to the chemical industry, or to both. It would be rational merely to make the acetate and spin it, but, on one hand, the processes involved in the recovery for re-use of the chemicals required make it attractive to make these chemicals as well, whilst on the other, there is the temptation to dye and do much else with the rayon, even to the making of dyestuffs. In some quarters the view is gaining ground that it is more economic in this and analogous industries to restrict the number of operations than to enter too far into the chemical industry, except on a large scale.

The book follows normal lines in the treatment: commencing with an historical section, a description of modern views of the structure of cellulose and its acetate follows, after which the practical side is stressed. The details are sufficient to be of material help in initiating and running a factory, the chapter under this heading being clearly written. Nothing that is of interest in connexion with cellulose acetate is omitted, so far as we have been able to judge, and the latest plant for special purposes, such as active carbon for solvent recovery and the Suida process for acetic acid recovery, are adequately described. The book should be of immediate use to all who are active or seek for information in this field.

Some Ancestral Fossil Mammals

British Museum (Natural History). Catalogue of the Pontian Carnivora of Europe in the Department of Geology. By Dr. Guy Ellcock Pilgrim. Pp. vi + 174 + 2 plates. (London: British Museum (Natural History), 1931.) 15*s.*

At the time of publication of Darwin's "Origin of Species", Prof. Albert Gaudry, of Paris, was collecting and studying a large series of remains of fossil mammals from an Upper Miocene or Lower Pliocene freshwater deposit at Pikermi, near Athens, in Greece. He soon recognised that, although the animals represented by his fossils were closely similar to those inhabiting the warmer parts of the Old World at the present day, they differed in several small respects and seemed to include some links between animals which are now very distinct, and others which might be the ancestors of our modern animals. Between 1862 and 1867 he published his results in a classic volume entitled "Animaux fossiles et géologie de l'Attique", which was the first attempt on a large scale to describe and arrange extinct animals from the point of view of an evolutionist. Since Gaudry's pioneer work, nearly similar groups of fossil mammals have been found in Spain, Hungary, Macedonia, the Black Sea region, Persia, Mongolia, eastern China, and India; while apparently contemporaneous deposits in North America have yielded several closely allied genera and species. These mammals constitute the fauna which is now generally known as Pontian, and they include especially numerous individuals of the three-toed horse, *Hipparion*.

For many years Dr. G. E. Pilgrim has studied the Pontian and later fossil mammals in India, and he is at present preparing a descriptive catalogue of the large collections of similar fossils from Pikermi, the island of Samos, and other European localities, which are brought together in the British Museum. The first volume, on the Bovidæ. was published in 1928, and the second volume, on the Carnivora, is now before us.

Dr. Pilgrim's descriptions, of course, are entirely technical, but they are extended by many interesting comparisons which help to make the new facts useful for science. They are illustrated by some good text-figures and two plates. The first section relates to the primitive forerunners of the dogs and bears, which are important among the fossils from Pikermi. The next long section is on the mustelines and otters, which are less differentiated in the Pontian fauna than they are at the present day. Then follow more annectant forms between viverrines and hyænas, besides both ancestral hyænas and true hyænas. The well-known *Hyæna eximia*, from Pikermi and Samos, is represented by many fine specimens, which seem to show that it belongs to the same genus as the spotted hyæna, usually named *Crocuta*. This genus is now known to have ranged as far as eastern China, and it is difficult to determine where it originated. True cats of the genus *Felis* occur, and with them are remains of *Machærodus* and other members of the sabre-toothed group.

Dr. Pilgrim's valuable catalogue is unfortunately marred a little by inadequate editing. There are more misprints than might be expected in a publication of the British Museum; and the statement on p. 142 that in 1857 the Bavarian Academy published its *Abhandlungen* in Vienna is inaccurate. There are several ungrammatical and inelegant expressions, and the text would have been much improved by the omission of redundant words and circumlocutions.

A. S. W.

Short Reviews

The Theory of Knowledge and Existence. By Dr. W. T. Stace. Pp. xii + 456. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 18*s.* net.

THIS comprehensive attempt to determine the characteristics and purpose of knowledge deserves careful reading. We believe that the author is right in stressing the empirical value of epistemology, though we fail to see why transcendental issues are altogether outside the horizon of the theory of knowledge proper. Adopting the well-known method of building up the world with some primitive elements, Dr. Stace characterises first the universe of the solitary mind, then gives shape to the external world, and finally describes what happens when the solitary mind discovers other minds. After concluding this part of his inquiry, he discusses space-time, mathematics, logic, the categories, and scientific knowledge. Though he purposely avoids the technicalities of these subjects, the author has many pertinent reflections about the issues they imply. To give but one example, in discussing the epistemological aspect of the new theories of matter, he points out that the earlier concept of the nuclear atom, though beyond any possible perception, is not itself unreal, as we can make a logical model of it by means of data supplied from other sources of perceptual knowledge. But the new concept of the 'wavicle' which purports to combine the characteristics of a particle with those of a wave, cannot possibly have any sort of existence, as it possesses contradictory properties. Also, he rightly assumes that when any type of knowledge clashes with logic, it is not logic but our scientific assumptions which must be changed somehow.

The author's views on the character of mathematics are of a more controversial character; for him, mathematical propositions are a necessity derived from logic. The truth or falsity of mathematics means something more than self-consistency; it refers them to reality outside mathematics; and therefore mathematics cannot exist in a world of its own, cut off from concrete things. Mathematics, like all other kinds of knowledge, is tied by the 'given'.

T. G.

Pétroles naturels et artificiels. Par J.-J. Chartrou. (Collection Armand Colin: Section de Chimie, No. 124.) Pp. 206. (Paris: Armand Colin, 1931.) 10.50 francs.

IN view of the rapidly growing importance of petroleum in modern life, M. Chartrou attempts to acquaint the public with the main features of the technique of the industry, which in France has only recently come into prominence. An interesting and readable account is given of the composition and properties of the natural deposits, the character of the soil and geological strata in which they occur, theories as to their origin, methods used in the exploitation, storage, transport, refining and analysis of the different products, their application to industry, together with brief summaries of geographical distribution, regulations imposed by different governments and the dangers associated with the operations. In the last chapter new processes are described which are being developed for the production of synthetic liquid fuels and petroleum substitutes.

A glance through the bibliography shows that the author has consulted mainly French works, though Redwood's treatise and several English and American journals are included. Much information of interest to the general reader has been compressed into a small compass and the result is an attractive volume, well illustrated with clear diagrams of apparatus and plant. The chapter on analysis summarises the methods used in the determination of chemical and physical properties of products, empirical formulæ being given for the calculation of constants. The book should appeal not only to technologists but also to a wider public.

Differential Equations from the Algebraic Standpoint. By Prof. J. F. Ritt. (American Mathematical Society, Colloquium Publications, Vol. 14.) Pp. x + 172. (New York: American Mathematical Society: Cambridge: Bowes and Bowes; Berlin: Hirschwaldsche Buchhandlung; Paris: Albert Blanchard; Milano: Nicola Zanichelli, 1932.) 2.50 dollars.

THIS book gives a connected account of the author's researches on the algebraic side of the theory of differential equations and forms a welcome addition to the literature of the subject, for this aspect of the theory has received little attention hitherto. About four-fifths of the space is devoted to ordinary and the remainder to partial algebraic differential equations, the treatment broadly speaking following the lines laid down by Kronecker and his successors in the theory of algebraic elimination and the general theory of algebraic manifolds, transcendental equations being excluded from consideration.

The first chapter is devoted to the decomposition of a system of ordinary algebraic differential equations into irreducible systems, and the second to the precise formulation of the notion of the general solution of a differential equation and its use in determining the manifold of an irreducible system. The succeeding chapters apply and develop these results, the last two extending them to systems of partial differential equations. The novelty of the point of view adopted and the importance of the results obtained render the book well worthy of the attention of all interested in the theory of differential equations.

First Principles of Television. By A. Dinsdale. Pp. xv + 241 + 38 plates. (London: Chapman and Hall, Ltd., 1932.) 12*s.* 6*d.* net.

IT is no easy matter to write a book on a subject like television which is making rapid progress. There is always the risk that when the work is on the eve of publication some new invention will render part of it antiquated. Something of this nature has occurred in this case. Only a few days before writing the preface, the author attended a demonstration in New York given by U. A. Sanabria, a young experimenter from Chicago, who presented 'close up' pictures on a screen six feet square which were better than anything he had ever seen before. By special neon arcs, special arrangements of holes in the discs and a special amplifier, Sanabria can produce pictures which show an almost complete absence of flicker and the detail of which is quite as good as that provided by the average home cinema. Seaming lines also are very little in evidence. We think it was wise to include in the preface what appears at first sight to be a technical afterthought. Anyone possessing some knowledge of electricity and radio can easily understand this book. We can recommend it to everyone who wants a general knowledge of the first principles of television given in an interesting and easily intelligible form.

Webster's Collegiate Dictionary. Fourth edition of the Merriam Series. Pp. xl + 1222. (London: G. Bell and Sons, Ltd.; Springfield, Mass.: G. and C. Merriam Co., 1932.) 21*s.* net.

FROM the point of view of students of science, technology, etc., we cannot think of a better book of general reference. Besides the normal English words to be expected in a dictionary of this size, there are many scientific, technical, and mythological names which they may have occasion to verify, and most of them are included. In this respect the volume is surprisingly up to date, though there are a few omissions. For example, isotopes and stomates (instead of the older term, stomata), are now familiar terms, yet they do not appear. Also protein has been substituted for proteid, yet the latter term takes precedence in this dictionary and is used throughout, in definitions. These, however, are minor points in an extremely useful reference volume which has clearly involved much care and labour. The book is well bound; but we think a cheaper edition is desirable.

Mental Deficiency Practice: the Procedure for the Ascertainment and Disposal of the Mentally Defective. By Dr. F. C. Shrubsall and A. C. Williams. Pp. vii + 352. (London: University of London Press, Ltd., 1932.) 12*s.* 6*d.* net.

THE subject of mental defect is very slow in coming before the public. So many individuals prefer to repress the subject and not admit its existence. It is, however, a very serious problem and one which so many local authorities have shirked and left in a disgraceful condition. Dr. Shrubsall, who is lecturer in mental deficiency in the University of London, and Dr. Williams, have given us a very useful and practical book in which the procedures for ascertainment and disposal of the mental defective in our midst are set out in a very sensible and clear manner.

The pages devoted to specimen forms and their use should be most helpful to those who may have doubts and difficulties.

Light and Life*

By PROF. N. BOHR, For.Mem.R.S.

THIS revision of the foundations of mechanics, extending to the very question of what may be meant by a physical explanation, has not only been essential, however, for the elucidation of the situation in atomic theory, but has also created a new background for the discussion of the relation of physics to the problems of biology. This must certainly not be taken to mean that in actual atomic phenomena we meet with features which show a closer resemblance to the properties of living organisms than do ordinary physical effects. At first sight, the essentially statistical character of atomic mechanics might even seem difficult to reconcile with an explanation of the marvellously refined organisation, which every living being possesses, and which permits it to implant all the characteristics of its species into a minute germ cell.

We must not forget, however, that the regularities peculiar to atomic processes, which are foreign to causal mechanics and find their place only within the complementary mode of description, are at least as important for the account of the behaviour of living organisms as for the explanation of the specific properties of inorganic matter. Thus, in the carbon assimilation of plants, on which depends largely also the nourishment of animals, we are dealing with a phenomenon for the understanding of which the individuality of photo-chemical processes must undoubtedly be taken into consideration. Likewise, the peculiar stability of atomic structures is clearly exhibited in the characteristic properties of such highly complicated chemical compounds as chlorophyll or hæmoglobin, which play fundamental rôles in plant assimilation and animal respiration.

However, analogies from chemical experience will not, of course, any more than the ancient comparison of life with fire, give a better explanation of living organisms than will the resemblance, often mentioned, between living organisms and such purely mechanical contrivances as clockworks. An understanding of the essential characteristics of living beings must be sought, no doubt, in their peculiar organisation, in which features that may be analysed by the usual mechanics are interwoven with typically atomistic traits in a manner having no counterpart in inorganic matter.

An instructive illustration of the refinement to which this organisation is developed has been obtained through the study of the construction and function of the eye, for which the simplicity of the phenomena of light has again been most helpful. I need not go into details here, but shall just recall how ophthalmology has revealed to us the ideal properties of the human eye as an optical instrument. Indeed, the dimensions of the interference patterns, which on account of the wave nature of light set the limit for the image formation in the eye, practically coincide with the size of such partitions of the retina which have separate nervous connexion with the brain. Moreover, since the absorption of a few light quanta, or perhaps of only a single quantum, on such a retinal partition is sufficient to produce a sight impression, the sensitiveness of the eye may even be said to have reached the limit imposed by the atomic character of the light effects. In both respects, the efficiency of the eye is the same as that of a good telescope or microscope, connected with a suitable amplifier so as to make the individual processes observable. It is true that it is possible by such instruments essentially to increase our powers of observation, but, owing to the very limits imposed by the properties of light, no instrument is imaginable which is more efficient for its purpose than the eye. Now, this ideal refinement of the eye, fully recognised only through the recent development of physics, suggests that other organs also, whether they serve for the reception of information from the surroundings or for the reaction to sense impressions, will exhibit a similar adaptation to their purpose, and that also in these cases the feature of individuality symbolised by the quantum of action, together with some amplifying mechanism, is of decisive importance. That it has not yet been possible to trace the limit in organs other than the eye, depends solely upon the simplicity of light as compared with other physical phenomena.

The recognition of the essential importance of fundamentally atomistic features in the functions of living organisms is by no means sufficient, however, for a comprehensive explanation of biological phenomena. The question at issue, therefore, is whether some fundamental traits are still missing in the analysis of natural phenomena, before we can reach an understanding of life on the basis of physical experience. Quite apart from the practically inexhaustible abundance of biological phenomena, an answer to this question can scarcely be given without an examination of what we may understand by a physical explanation, still more penetrating than that to which the discovery of the quantum of action has already forced us. On one hand, the wonderful features which are constantly revealed in physiological investigations and differ so strikingly from what is known of inorganic matter, have led many biologists to doubt that a real understanding of the nature of life is possible on a purely physical basis. On the other hand, this view, often known as vitalism, scarcely finds its proper expression in the old supposition that a peculiar vital force, quite unknown to physics, governs all organic life. I think we all agree with Newton that the real basis of science is the conviction that Nature under the same conditions will always exhibit the same regularities. Therefore, if we were able to push the analysis of the mechanism of living organisms as far as that of atomic phenomena, we should scarcely expect to find any features differing from the properties of inorganic matter.

---

* Continued from p. 423

With this dilemma before us, we must keep in mind, however, that the conditions holding for biological and physical researches are not directly comparable, since the necessity of keeping the object of investigation alive imposes a restriction on the former, which finds no counterpart in the latter. Thus, we should doubtless kill an animal if we tried to carry the investigation of its organs so far that we could describe the rôle played by single atoms in vital functions. In every experiment on living organisms, there must remain an uncertainty as regards the physical conditions to which they are subjected, and the idea suggests itself that the minimal freedom we must allow the organism in this respect is just large enough to permit it, so to say, to hide its ultimate secrets from us. On this view, the existence of life must be considered as an elementary fact that cannot be explained, but must be taken as a starting point in biology, in a similar way as the quantum of action, which appears as an irrational element from the point of view of classical mechanical physics, taken together with the existence of the elementary particles, forms the foundation of atomic physics. The asserted impossibility of a physical or chemical explanation of the function peculiar to life would in this sense be analogous to the insufficiency of the mechanical analysis for the understanding of the stability of atoms.

In tracing this analogy further, however, we must not forget that the problems present essentially different aspects in physics and in biology. While in atomic physics we are primarily interested in the properties of matter in its simplest forms, the complexity of the material systems with which we are concerned in biology is of fundamental significance, since even the most primitive organisms contain a large number of atoms. It is true that the wide field of application of classical mechanics, including our account of the measuring instruments used in atomic physics, depends on the possibility of disregarding largely the complementarity, entailed by the quantum of action, in the description of bodies containing very many atoms. It is typical of biological researches, however, that the external conditions to which any separate atom is subjected can never be controlled in the same manner as in the fundamental experiments of atomic physics. In fact, we cannot even tell which atoms really belong to a living organism, since any vital function is accompanied by an exchange of material, whereby atoms are constantly taken up into and expelled from the organisation which constitutes the living being.

This fundamental difference between physical and biological investigations implies that no well-defined limit can be drawn for the applicability of physical ideas to the phenomena of life, which would correspond to the distinction between the field of causal mechanical description and the proper quantum phenomena in atomic mechanics. However, the limitation which this fact would seem to impose upon the analogy considered will depend essentially upon how we choose to use such words as physics and mechanics. On one hand, the question of the limitation of physics within biology would, of course, lose any meaning, if, in accordance with the original meaning of the word physics, we should understand by it any description of natural phenomena. On the other hand, such a term as atomic mechanics would be misleading, if, as in common language, we should apply the word mechanics only to denote an unambiguous causal description of the phenomena.

I shall not here enter further into these purely logical points, but will only add that the essence of the analogy considered is the typical relation of complementarity existing between the subdivision required by a physical analysis and such characteristic biological phenomena as the self-preservation and the propagation of individuals. It is due to this situation, in fact, that the concept of purpose, which is foreign to mechanical analysis, finds a certain field of application in problems where regard must be taken of the nature of life. In this respect, the rôle which teleological arguments play in biology reminds one of the endeavours, formulated in the correspondence argument, to take the quantum of action into account in a rational manner in atomic physics.

In our discussion of the applicability of mechanical concepts in describing living organisms, we have considered these just as other material objects. I need scarcely emphasise, however, that this attitude, which is characteristic of physiological research, involves no disregard whatsoever of the psychological aspects of life. The recognition of the limitation of mechanical ideas in atomic physics would much rather seem suited to conciliate the apparently contrasting points of view which mark physiology and psychology. Indeed, the necessity of considering the interaction between the measuring instruments and the object under investigation in atomic mechanics corresponds closely to the peculiar difficulties, met with in psychological analyses, which arise from the fact that the mental content is invariably altered when the attention is concentrated on any single feature of it.

It will carry us too far from our subject to enlarge upon this analogy which, when due regard is taken to the special character of biological problems, offers a new starting point for an elucidation of the so-called psycho-physical parallelism. However, in this connexion, I should like to emphasise that the considerations referred to here differ entirely from all attempts at viewing new possibilities for a direct spiritual influence on material phenomena in the limitation set for the causal mode of description in the analysis of atomic phenomena. For example, when it has been suggested that the will might have as its field of activity the regulation of certain atomic processes within the organism, for which on the atomic theory only probability calculations may be set up, we are dealing with a view that is incompatible with the interpretation of the psycho-physical parallelism here indicated. Indeed, from our point of view, the feeling of the freedom of the will must be considered as a trait peculiar to conscious life, the material parallel of which must be sought in organic functions, which permit neither a causal mechanical description nor a physical investigation sufficiently thorough-going for a well-defined application of the statistical laws of atomic mechanics. Without entering into metaphysical speculations, I may perhaps add that any analysis of the very concept of an explanation would, naturally, begin and end with a renunciation as to explaining our own conscious activity.

In conclusion, I wish to emphasise that in none of my remarks have I intended to express any kind of scepticism as to the future development of physical and biological sciences. Such scepticism would, indeed, be far from the mind of a physicist at a time when the very recognition of the limited character of our most fundamental concepts has resulted in such far-reaching developments of our science. Neither has the necessary renunciation as regards an explanation of life itself been a hindrance to the wonderful advances which have been made in recent times in all branches of biology and have, not least, proved so beneficial in the art of medicine. Even if we cannot make a sharp distinction on a physical basis between health and disease, there is, in particular, no room for scepticism as regards the solution of the important problems which occupy this Congress, as long as one does not leave the highroad of progress, that has been followed with so great success ever since the pioneer work of Finsen, and which has as its distinguishing mark the most intimate combination of the study of the medical effects of light treatment with the investigation of its physical aspects.

Food Storage at Low Temperature

SOME of the problems involved in the preservation of food for transport and storage have been discussed by Sir William Hardy in two recent lectures*. The abandonment of the earlier agricultural civilisation by many races for an urban culture required the transportation for long distances of foodstuffs destined for the peoples of the cities. Non-perishable foods such as oil, honey and grain required no special treatment; meat and fish, however, were preserved by drying or curing with salt, and root vegetables for winter use as jams made with honey. It was not until the eighteenth century that the growth of winter vegetables was developed and another hundred years passed before low temperature began to be employed to preserve perishable food in the fresh condition.

The modern period began about fifty years ago, when the first cargo of meat was successfully brought from Australia in the frozen condition. That was made possible by mechanical refrigeration, and, at first, research and invention were occupied in perfecting the machinery, the insulation and the design of cold stores, in wagons or in ships. The properties of the material to be stored were, on the whole, neglected until more recently, when the importance of defining the exact conditions under which the stored foodstuffs survived for the longest time was realised and the science of biological engineering became differentiated from mechanical engineering.

The heavily insulated rooms at the Low Temperature Research Station at Cambridge are cooled by pipe grids through which cold calcium chloride brine is pumped. The first approximation to the required temperature is arrived at by regulating the temperature and rate of flow of the brine. The fine adjustment is made by treating the chamber as an electrically controlled thermostat.

Stored foodstuffs undergo changes in cold storage, the nature of which must be fully understood if the food is to be stored at the optimum temperature and if the store is to function efficiently. Fruit, for example, is alive, consuming oxygen and giving off carbon dioxide and heat. The heat production is greater the higher the temperature and is also increased by disease, for example, fungus rot. A rise of temperature in the store thus sets up vicious circles, with shortening of the storage life of the fruit. In addition to removal of heat from the store, the engineering problems involve the maintenance therein of an atmosphere with a constant content of oxygen, carbon dioxide and water vapour.

A further complication arises from the fact that storage life also varies, under the same conditions, with the earlier history of the fruit. The following variables have been found to affect the storage life of apples: variety, rootstock and age of tree, maturity of fruit on tree, its size and position on the inflorescence, the soil, manuring and climate, and finally orchard sanitation.

The rate of output of carbon dioxide on storage varies with the temperature, but the curves at different temperatures all have the same shape. The output falls continuously while the apple is growing and maturing on the tree. It then rises for a short time after picking and again decreases during the remainder of storage life. The similarity of the curves of output at different temperatures suggests that it must be governed by one factor only. This may be the rate of diffusion of oxygen —not of carbonic acid because it diffuses so much more rapidly—or the semi-permeability of the skin of the fruit to the respiratory gases. During the earlier period of storage the apple is peculiarly susceptible to the injury of internal breakdown; during the later period it is only slightly susceptible to internal breakdown but increasingly liable to attack by fungi. For Bramley's Seedling it has been found that minimum wastage from both these factors occurs at 3° C. which is therefore the optimum temperature for storage of this variety.

---

* The Hurter memorial lecture before the Liverpool Section of the Society of Chemical Industry on November 18, 1932 (*Chem. and Ind.*, 52, 45; 1933). The Sir William Trueman Wood lecture before the Royal Society of Arts on February 22, 1933.

Another aspect which must be considered is the fact that apples give off vapours or emanations in minute amounts, which are poisonous to other fruit, one part in about fifty thousand being a toxic dose. The phenomenon has a commercial interest since the emanation tends to quicken the ripening of young apples, so that a colony of apples tends to ripen at the same time.

Meat and fish may be either chilled or frozen. Fruit, of course, unless intended for some secondary process such as jam-making, must not be frozen. Chilling will only delay the growth of moulds or bacteria long enough to give the material a storage life of about 30–40 days. If it cannot be marketed within this time, it is necessary to freeze it. Freezing, however, alters the physical state of the tissues and yet does not abolish all chemical change. Moulds, for example, can grow down to $-7°$ C. and bacteria down to $-3°$ C. Freezing results in the separation of ice within the tissue. It acts therefore as a drying agent by withdrawing water. The proteins of muscle become increasingly insoluble when meat is stored in the frozen state, so that on thawing the product is tough and unpalatable. The rate of change has been found to be greatest at about $-3°$ C. The change is entirely due to freezing and does not occur when the tissue is merely overcooled to this or even a lower temperature.

Detailed study of the changes occurring in muscle in the cold has shown that overcooling to $-4°$ C. does not prevent return to the normal state on thawing. Freezing at this temperature kills the muscle, which becomes opaque, shortened and acid due to the formation of lactic acid. This acid is produced and accumulates even in the frozen state, the rate of accumulation rising to a maximum at about $-2°$ C. The temperature of $-1{\cdot}6°$ C. is critical. When frozen at a higher temperature the muscle can get rid of the excess lactic acid and revert to normal on thawing. Muscles frozen at a lower temperature have lost this power; they are dead on thawing and the acid increases in them as in *rigor mortis*. Thus at $-1{\cdot}6°$ C. the catalysts responsible for the re-synthesis of the lactic acid to glycogen are destroyed. It has also been found that the catalysts responsible for the synthesis of phosphagen are permanently lost at $-2{\cdot}5°$ C. and those concerned in the oxidation of lactic acid at $-3{\cdot}2°$ C.

In conclusion, Sir William Hardy referred to the difficulty of assessing the dietetic value of different foodstuffs. Experiments with human beings, which are costly and difficult, will no doubt give an answer in digestible calories which will be quite decisive, but there is little doubt that the answer in terms of human wellbeing will be indecisive. There are certain properties of foodstuffs, hard to define, which yet play their part in the assessment of the suitability of these foods for human consumption. 'Bloom' in meat is a case in point: it appears to have no obvious relation to digestibility, yet it is inadvisable to dismiss the judgment of the trade expert as devoid of physiological meaning. It is never safe to dismiss the tradition of the practical man as having no scientific basis.

Obituary

DR. H. O. FORBES

DR. HENRY OGG FORBES, who died at Selsey on October 27, 1932, was well known among travellers and naturalists in the latter part of the last century, but his activities had been for many years cut short by constant ill-health and consequent seclusion. The second son of the Rev. Alexander Forbes of Dunblade, Aberdeenshire, he was born on January 30, 1851, and educated at Aberdeen Grammar School and afterwards at the Universities of Aberdeen and Edinburgh. He proposed to enter the medical profession, but owing to the accidental loss of an eye, he abandoned this career, although he had almost completed the necessary examinations.

Forbes's earliest travels were in Portugal where he made biological and geological investigations; but in 1878 he embarked on an expedition to the Far East where he spent five years wandering among the Dutch islands—Java, Sumatra, Banda, Amboina, Timor-Laut, Buru and Timor—making observations and collecting zoological and other material. After his return to England, he published in 1885 his well-known volume: "A Naturalist's Wanderings in the Eastern Archipelago: a Narrative of Travel and Exploration from 1878 to 1883." Mrs. Anna Forbes wrote a book "Insulinde" (1887) giving her experiences of this expedition.

Forbes went to British New Guinea in 1885 and early in 1886 made an expedition inland from Port Moresby, hoping to ascend the Owen Stanley Range. Through no fault of his he was unsuccessful, but he made large botanical and other collections and entered into friendly relations with the Sogeri. Mr. John Douglas, the Administrator, appointed Forbes as the Government representative in the China Straits, and Mr. and Mrs. Forbes arrived at Samarai in June, where they remained until the end of March 1887. Forbes then went to Australia to arrange for another expedition. He left Port Moresby for the interior in October 1887 and again reached the base of the Range, making further geographical and other observations. An account and a map of this unsuccessful attempt to reach the summit of the Owen Stanley Range will be found in the *Scottish Geographical Magazine*, 4, 138, 1888. Sir William Macgregor succeeded in reaching the summit in 1889 and renamed it Mount Victoria; in his account of the expedition he criticised the work of Forbes (*Proc. Roy. Geog. Soc.*, 12, 218; 1898). This led to a reply by Forbes (loc. cit., p. 558), and Coutts Trotter later attempted to reconcile the two accounts (loc. cit., p. 697). Although Forbes visited various parts of New Guinea he did not publish anything about the natives in scientific journals, but he recorded a few notes in his official reports (New Guinea, Further Correspondence, C. 5883, London, 1890).

In 1890, Forbes was appointed director of the Canterbury Museum at Christchurch, New Zealand. During his stay there, he visited the Chatham Islands and made a study of the very interesting extinct birds found in recent deposits in that group. The results of this investigation will be found in a paper published in the *Ibis* for 1893, while his more theoretical views as to the geological history of this island group as deduced by a study of the recent and extinct fauna formed the basis for a paper published in the *Supplementary Papers* of the Royal Geographical Society, for which he received the award of the Gill Memorial.

In 1894, Dr. Forbes was appointed director of the Liverpool Museums, the interests of which he was energetic in promoting, and about this time he made, in company with the late Mr. W. R. Ogilvie-Grant, an expedition to the Island of Socotra, where large collections were made for the British Museum (Natural History) and for the Liverpool Museum; the results of this will be found in the "Natural History of Sokotra and Abd-el-Kuri: a Monograph of the Islands", published in 1903.

Forbes's last expedition was to Peru to investigate the condition of the guano industry and the best means for the conservation of the bird life on which the industry was dependent of the Guano Islands off the coast. This was undertaken on behalf of the Peruvian Government, for which a valuable report was prepared containing a survey of the islands, and suggestions for the most efficient methods of working the deposits.

From the University of Aberdeen, Forbes received an honorary degree of LL.D. He was a fellow of the Royal Geographical Society and of the Zoological Society, as well as of many other learned bodies.

Dr. R. T. A. Innes

Robert Thorburn Ayton Innes was born in Edinburgh and educated in Dublin. In 1879, at the age of seventeen years, he became a fellow of the Royal Astronomical Society. He was married in London and began his career as a double star observer in Sydney, where he soon became of repute among astronomers. Half a dozen years later he deliberately sacrificed his quite considerable material prosperity in order to become temporary clerical assistant to Sir David Gill at the Royal Observatory, Cape of Good Hope, at a salary just one-tenth of his income in New South Wales. No weak, 'Safety First' principle in this sudden plunge but everything he had, wife, family, capital and reputation, risked. In after years it gave Sir David pleasure to record the insatiable appetite of his 'Secretary, Librarian and Accountant' for work, extra work and yet more work.

During these few years Innes used the 18-inch Victoria telescope in an extensive search for double stars, but his main work was in the revision of the Cape Photographic Durchmusterung, in which Gill years earlier had the co-operation of Kapteyn. The importance of the C.P.D. may be judged by the award in 1902 of the gold medal of the Royal Astronomical Society to Kapteyn. In this work and for his observation of variable stars Innes used the 7-inch equatorial by Merz which dated from 1849 and Gill wrote, "This work of Mr. Innes was from first to last a labour of love, carried out by him with conspicuous energy and success." It would be difficult to over-estimate the value of this period of testing when Innes was acquiring the knowledge and experience and habits of methodical industry which procured him in 1903 the unsolicited post of creator of the Transvaal Observatory.

The Boer War emancipated the Dutch of South Africa from the tutelage of President Kruger, and at its conclusion an intellectual awakening demanded the establishment of the Transvaal Observatory, which must surely be regarded as the first fruits of that war. For a time at least, it was intended that this Observatory should be exclusively devoted to meteorology with an indispensable time department. Except as a step-ladder by which to raise himself to higher levels, meteorology, whether theoretical or observational, had no appeal for Innes. "Here," said he, in effect, "is a fine clear sky with steady observational conditions, let me use my telescope without stopping to inquire as to how these conditions arose." His first step upon appointment was the purchase (how, we know not, but probably his family had to endure 'iron rations' for a time) of a 9-inch refractor to be mounted on an equatorial stand borrowed from his benefactor at the Cape. In 1909, after an interval of six years, Innes persuaded the authorities to provide him with funds for a 26-inch refractor—this in itself was a difficult piece of work. It was expected that this worthy instrument would be in use in a couple or three years at the most but here is the tragedy of the life of Innes. For sixteen years he was fretting and chafing at the delay, for his telescope was not erected complete with the object glass fitted until April 1925, only two years and nine months before his retirement at the age of sixty-six years.

Innes's first communication made to the *Monthly Notices of the Royal Astronomical Society* was to correct a computational slip in Laplace. From Sydney there followed two others on the secular perturbations of the orbit of the earth by Mars and by Venus, and by a third on the methods of Gauss. It was from New South Wales too that he published his first discovery of 26 new double stars using a 6-inch equatorial without circles. This result of thirty hours observation, "will prove what a mine of wealth awaits the diligent double-star observer in the southern hemisphere". Prophetic words, for ultimately his own doubles numbered 1,200. Next at the Cape he observed η Argus and in a few years discovered 285 new doubles and published his catalogue of southern double stars. Besides this work he contributed two papers to the *Monthly Notices* on multiple systems, and a very notable communication on Jacobi's 'Nome' as a means of computing elliptic integrals.

At Johannesburg Innes established his well-known Circulars which contain the records of much of his work—but the *Proceedings of the Royal Society of Edinburgh*, *Astronomische Nachrichten*, and *Astronomical Journal* contain papers of value. His interest in celestial mechanics continued unabated but of necessity other subjects demanded and received due attention—to mention a few: Jupiter's Galilean satellites, galactic co-ordinates, variable rotation of the earth, occultations and their reduction by improved methods, continuation and completion of the work of Franklin-Adams, use of blink microscope, the invariable plane of the solar system, a new catalogue of southern double stars, and comet orbits. It was a proud day for Innes when the University of Leyden gave him the D.Sc. (*honoris causa*) and of all his work perhaps his discovery of Proxima Centauri pleased him most.

Innes was a good friend and the wide extent of his generosity is barely suspected. In spite of his advancement, he remained to the end absolutely simple, approachable and unaffected and apparently unaware of the high regard in which he was held. Deeply interested in the work of others, he himself worked until the day of his sudden and quite unexpected death on Monday, March 13.

FRANK ROBBINS.

WE regret to announce the following deaths:

Lieut.-Col. A. W. Alcock, C.I.E., F.R.S., professor of anthropology in the London School of Hygiene and Tropical Medicine and professor of medical zoology in the University of London, from 1919 until 1924, formerly superintendent of the Indian Museum and professor of zoology in the Calcutta Medical College, known for his work on Crustacea and deep-water fishes, on March 24, aged seventy-three years.

Mr. James Groves, an authority on the *Charophyta*, on March 20, aged seventy-five years.

Prof. Friedrich Rinne, formerly professor of mineralogy and petrography in the University of Leipzig, author of many works on crystallography, on March 12, aged seventy years.

Prof. Edwin C. Starks, associate professor of zoology in Stanford University, California, who was a corresponding member of the Zoological Society of London, aged sixty-six years.

Prof. J. Millar Thomson, F.R.S., emeritus professor of chemistry at King's College, London, president of the Institute of Chemistry of Great Britain and Ireland in 1900–3, who was known for his work on the chemistry of ancient glasses, chemistry of pigments, etc., on March 22, aged eighty-four years.

News and Views

Early Man in East Africa

WHILE it is no longer possible on the latest interpretation of the evidence to accept the very high antiquity of Oldoway man, there appears elsewhere in this issue of NATURE (p. 477) a series of reports on the further evidence collected by Dr. Leakey in the spring of last year (not "autumn" as stated inadvertently in our note last week) which points to the early appearance of *Homo sapiens* in East Africa. We publish in full the reports of four committees, each dealing with one aspect of the evidence, presented to, and adopted by, the Royal Anthropological Institute's conference at Cambridge. The material which the committees had before them was derived from deposits at Kanjera and Kanam, two sites, about three miles apart, near Kendu, at the north-east of Victoria Nyanza, an area of old lake-beds, well-known for its fossiliferous deposits. It comprised a part of a femur and fragments of human skulls of three individuals from Kanjera, of which one group formed a skull-cap, and a second permitted a reconstruction of the skull, and of a small fragment of human mandible from Kanam, fossil animal remains, including a considerable proportion (which has been put so high as fifty per cent) of specimens belonging to extinct forms, and two stone industries, one a pebble industry and the other Chellean. It is to be noted that at Kanjera, while the human bones comprising two groups had been washed out by the rains, two fragments of the third group were found *in situ* in association with fossil animal remains and Chellean tools. Further, the Kanam fragment of mandible was found not far from a pre-Chellean stone implement.

IN considering the findings of the committees, it must be borne in mind that the geological evidence, more especially in its stratigraphical aspect, is crucial. Several members of the geological committee have visited the sites personally and concur with Dr. Leakey in his view that after the Kanjera and Kanam deposits had been laid down there was great local tilting and volcanic activity. The committee "does not believe that the [skeletal] fragments can have been introduced into the calcareous deposit at a later date . . . the two fragments said to be found *in situ* belong in fact to the original deposit". The palæontological committee finds that the fragment of human jaw from Kanam was associated with a fossil fauna which justifies its reference to the lower Pleistocene, while the Kanjera fauna "cannot be later than the middle Pleistocene". Thus from these two findings it appears that the human remains are referable on both geological and palæontological grounds to lower and middle Pleistocene dates. As to the character of the human remains, the report of the anatomical committee is not unfavourable to their high antiquity, so far as can be determined by their condition, points out the absence of Neanderthaloid characters, and, while adverting to the abnormal thickness of one of the skulls, sees no feature inconsistent with their inclusion in the type of *Homo sapiens*. On the archæological evidence, the human skeletal remains, thus regarded as within the category of 'modern man', are associated with what for this purpose may be termed a pre-Chellean, and a Chellean industry, which are equated with the cultures of Europe of like character through the Oldoway series. The latter are said to be of equal or somewhat greater antiquity than those with which they are comparable in Western Europe. It is to be noted that, archæologically, the association of the Kanam jaw fragment with a pebble industry assigns it to Oldoway I, a stage earlier than that with which Oldoway man was originally associated—the later phase of Oldoway II.

Control of the Tsetse Fly

ONE of the most terrible scourges of Africa is the disease known as sleeping sickness, which is caused by a trypanosome, a blood-parasite, carried and spread by two species of tsetse fly. Hence there was a large gathering of the fellows at the meeting of the Zoological Society on March 21 to see the film exhibited by Mr. R. W. Harris, who showed what is being done by the Government entomologists to mitigate, if not terminate, the ravages of this insect. Since this war of extermination has to be carried on over millions of square miles, any such campaign might seem hopeless. But it was made manifest that, in so far as Rhodesia is concerned, a considerable measure of success has been attained. This has been done by the use of an ingenious trap devised by Mr. Harris's father, Mr. R. H. T. P. Harris. The trap is made of canvas; box-like in form, and much wider at the top, it is mounted on four legs, keeping it well off the ground. In bulk it is roughly of the size of, say, a small antelope. The flies are not very discriminating, and on sighting this canvas 'stalking-horse' alight on it, and crawl down according to their habit, to reach the shaded under-side, there to suck the blood of their prospective victim. Their exploration is thorough, but fruitless. But presently, they find a long slit through which daylight appears, entering from a special cage at the top. They at once pass through, and upwards, into what they take to be the daylight and freedom beyond. Passing into this light-filled cage they are unable to escape. Enormous heaps of flies were shown which had been taken from this trap. Yet another trap was shown designed to induce the flies to deposit their larvæ therein. Millions of pupæ are taken in this way.

DR. BEVAN joined with Major Austen, who forcefully reviewed the main results of this work at the end of the paper, by deploring the efforts which have been made to control the tsetse fly by killing off big game animals. More than 15,000 head of game in one year were slaughtered to this end. This takes no account of the numbers which died from wounds, owing to the lack of skill of the natives armed for this purpose. This state of affairs has fortunately been stopped, for a period at least, owing to the need for financial economy. It is the more deplorable because, as Major Austen and others have shown, if the very last of the big game animals of Africa was wiped out, sleeping sickness would still remain, since there are numerous small animals which also act as hosts for the trypanosome concerned. Even now, considerable misapprehension exists as to tsetse flies. Commonly one hears of *the* tsetse fly. As a matter of fact there are twenty species, all of which feed on blood. Only some of these depend for their food on game animals. *Glossina palpalis*, carrying *Trypanosoma gambiense* and *G. morsitans*, carrying *Trypanosoma rhodesiense*, are the most formidable of sleeping sickness disseminators. But, as Duke and Swinnerton have shown, in certain circumstances, *G. swynnertoni*, closely allied to *G. morsitans*, may also cause human trypanosomiasis, or sleeping sickness. Dr. Bevan gave a most helpful and interesting summary of what is being done in the suppression of this scourge, and the methods adopted towards that end. It is devoutly to be hoped that his protest against the wholesale slaughter of game, as a means to that end, will now cease, since all the highest authorities agree that even if successful, it would be a futile measure. More than that, as evidence has already shown, it might lead to an aggravation of the evil.

The Kea Parrot

WHETHER or not we may be able to boast 'home-bred' keas depends on an experiment about to be made at the Gardens of the Zoological Society of London. An artificial cave is to be made in the parrot-house to induce, if possible, a pair of these birds to breed, and it may well be successful. The kea parrot of New Zealand was years ago to be found in large numbers. Then, unfortunately, it took to attacking sheep, tearing holes in the back to get at the flesh, with fatal results to the sheep. It was said to do this for the sake of getting at the fat covering the kidneys, but this, obviously, is a statement founded on insufficient knowledge of what this implies. The damage done, as evidence has shown, was grossly exaggerated, and, when inflicted, was due to hunger. It was shown that keas could, and did, exist in numbers, without doing damage in areas where the food supply was constant, although in and around sheep-farms. But be this as it may, the fear and dislike which its presence has engendered, threatens its existence. Hence it is to be hoped the experiment of the Zoological Society will be successful.

Alcohol-Petrol as a Motor Fuel

IN connexion with the leading article in NATURE of March 11 on the subject of power alcohol, it is of interest to find that an alcohol-petrol mixture has begun to be distributed in Great Britain from garages over a wide and extending area under the name of "Koolmotor Alcohol Blend" at the same price per gallon as No. 1 Petrol. A mixture of alcohol in petrol has been in common use in racing cars for a year or two, but now the ordinary public will have for the first time an opportunity of testing its merits, in particular the absence of knocking. The anti-knock value is said to be equivalent to approximately 85 octane number. An alcohol of 99·9 per cent purity produced in England is being used. It is probable that the use of a fuel of this type in England, with the opportunity it will give for general experimenting, will have an effect on engine design. As the result of motor racing, which has as its real object the improvement of design and not the establishing of speed records, engines of high compression ratios have been introduced which need special fuels if they are to be used to advantage.

A BLEND of alcohol with ordinary petrol has now been prescribed by law in Czechoslovakia. Science Service of Washington, D.C., gives details of the spirit, 20 per cent alcohol and 80 per cent petrol, which the Government has apparently instigated in order to give a boost to the potato industry. Potato starch yields the desired grade of alcohol by hydrolysis and fermentation and all motor fuel is, apparently, to be treated with the specified percentage of alcohol before retail sale. There is, further, one technical matter which seems to have been solved in this connexion. Alcohol, as produced by economical distillation methods, usually carries with it 4–6 per cent water, which makes it impossible to mix directly with straight-run petrol, particularly of the paraffin base type. Recent research has resulted in a new distillation process, economical on a large scale, which permits dry or 'absolute' alcohol to be made with the aid of benzene. This product is now available under the new Czechoslovakian edict. The somewhat curious corollary to all this is that ordinary petrol will now go on the restricted list in that country, like ethyl and methyl alcohol in Great Britain, and, presumably, only chemists, research laboratories and the like will be able to receive permits to purchase pure petrol.

Darwin's Barometer

THE British Association has recently received on loan from the Royal Society the barometer used by Charles Darwin during the voyage of the *Beagle*, and it is now exhibited among the other relics of Darwin in Down House, his home in Kent, now in the custody of the Association. The barometer, made originally by the firm of Newton, has been restored by Messrs. Negretti and Zambra with the advice of the Meteorological Office, the scales have been re-engraved, and it is now in working order as Darwin had it. The instrument is of the straight type, contained in a wooden case three feet long, with a thermometer near the base. The barometer scale reads down to 18·2 in., so it was suitable for use up to fairly high altitudes, and Darwin is known to have carried it when ashore during the voyage. A double mercury cistern and locking arrangement is provided to allow of carrying the instrument without disturbance.

British Polar Year Expedition

THE National Polar Year Committee has received a report dated December 31, 1932 from Mr. J. M. Stagg, leader of the British expedition at Fort Rae in Canada. From this it appears that the party had its first taste of winter conditions on October 1, when the first snow fell and the rain recorder was permanently frozen up. The temperature at the date of the report was about −40° F. Difficulties have also been experienced with the clocks. Special low temperature clocks proved useless out of doors, but the party found that by removing all the oil from ordinary clocks, they functioned satisfactorily. The recording pen of the anemograph has also proved troublesome. Sounding balloons have been sent up but none had been recovered, though a cabled message has since reported the recovery of two meteorographs with good records. Communication with the sub-station for auroral photography about twenty miles south-east of Fort Rae was by wireless, but with the onset of winter, a telephone line was taken across the frozen Great Slave Lake. Auroral activity has been poor though some form of aurora can be observed more or less continuously from dusk until dawn. Some four hundred photographs have been taken, using the double station communication to obtain simultaneous exposures at Fort Rae and the sub-station twenty miles distant. The moon is only below the horizon for a short time daily, and during full moon auroral photography becomes almost impracticable. The sub-station is manned by one member of the expedition for a week at a time. The expedition's schedule includes full meteorological records every three hours, hourly cloud observations, and observations of aurora every five minutes and continuously when photography is being done.

Recent Acquisitions of the British Museum (Natural History)

ADDITIONS to the study series of mammals in the Zoological Department of the Museum include the skins of a male and female golden cat (*Profelis aurata*) from the Cameroons, presented by Mr. F. W. Carpenter. The specimens illustrate the two colour phases found in this species, one skin being buff and the other grey. A similar dimorphism exists in the bay cat of Asia, and at one time the buff-coloured specimens were thought to represent a species distinct from the grey ones. The Department of Entomology has received during the past twelve months a further 7,773 insects collected and presented by Mr. Rowland Turner, from South Africa. Most of these are small and little-known wasps, and the proportion new to science is extremely high. The Department of Mineralogy has acquired by exchange fragments of a meteoric stone which fell on August 27, 1931, near Yukan in eastern Kiangsi, China. Although the fall of stones from the sky has been mentioned in Chinese literature since 1808 B.C., none appears to have been preserved with the exception of three stones that have been described scientifically since 1923.

Botanical Acquisitions at the Natural History Museum

His Majesty the King has placed on loan a further collection of Nepal plants presented to him by His Highness the Maharaja of Nepal. The collection contains 182 specimens and was made in central Nepal by Prof. K. N. Sharma. The plants are excellently preserved, and include a fine series of *Primula, Gentiana* and *Mecanopsis.* Seeds of most of the plants have been sent for growing in the Royal Parks and Gardens. The British herbarium of the late Mr. Percy Moring has been presented by his widow. Mr. Moring was resident for some time at Dover and the herbarium is rich in plants of the neighbourhood. It also contains the specimens collected round Hampstead during the Hampstead Regional Survey. Many specimens from the London suburbs are valuable records of habitats now lost through building. The Department has purchased Part I of a copy of an edition of Philip Miller's "Figures of Plants described in the Gardener's Dictionary", published in 1798. So far, nothing is known further about this edition. The thirty plates are printed in various colours and are also coloured; the dates have been erased from the blocks and the Linnean system of naming has been adopted.

A British Film Institute

The joint committee of the Commission on Educational and Cultural Films and the bodies representing the film trade has now reached agreement on a scheme for the setting up of a British Film Institute. The general purpose of this Institute will be to encourage the use and development of the cinematograph as a means of entertainment and instruction. Among its specific objects will be to advise educational institutions and other organisations and persons as to sources and conditions of supply, types of films and apparatus; to promote and undertake research into the various uses of the film and of allied visual and auditory apparatus; and to maintain a national repository of films of permanent value. The Institute will have a membership based on subscription, and its government will be vested in a council representative in equal proportions of the film trade, educational interests and the general public. The membership of the governing council has not yet been completed, but it includes Sir Charles Cleland, Mr. A. C. Cameron and Mr. R. S. Lambert as representing the Commission on Educational and Cultural Films and Mr. Thomas Ormiston, M.P., Mr. C. M. Woolf and Mr. S. Eckman, as representing the film trade.

Underground Lighting in Mines

The paper on "Underground Lighting in Mines" read to the South Wales Branch of the Association of Mining Engineers by R. H. Campin and published in the *Mining Electrical Engineer* for February is a helpful and useful paper. Special stress is laid on the importance of miners' hand lamps. Mr. Campin points out that most of the hand lamps now in use are virtually of the same type as those developed before 1915. There are approximately 750 thousand hand-lamps in use in Great Britain. About fifty per cent of them are flame safety lamps. The popularity of the flame type is probably due to the fact that it automatically indicates the presence of inflammable gas. Most of the electric lamps in use are of a somewhat antiquated type giving only one candle power and supplied by a two volt battery in a celluloid case. The number of lamps supplied by alkaline batteries is about four per cent. There is no doubt that in many cases improved lighting would considerably increase the output as well as diminish the total number of accidents per annum on which compensation has at present to be paid. The author mentions the case of a German mine where the effect of doubling the illumination was to increase the output per man-shift by about 30 per cent. Doubling the light increased the cost of the lighting from a halfpenny to a penny per ton of coal raised. Medical investigations have shown that nystagmus is practically a light deficiency disease. The collieries have to spend £440,000 annually in compensation to sufferers from it. If lights of not less than four candle power were used, the number of cases would be greatly diminished. The author thinks that the illumination of many of our collieries could be tripled or even quadrupled without increasing operating charges. Flood-lighting at localised spots is recommended.

Prehistoric Society of East Anglia

The contents of the recent issue of the *Proceedings of the Prehistoric Society of East Anglia* (vol. 7, pt. 1) are of exceptional interest. At the head is the presidential address in which Mr. J. Reid Moir surveys the evidence for the culture of Pliocene man which has been collected in the last twenty-five years. This is followed by a description by Mr. J. P. T. Burchell of hand-axes from the north of Ireland, upon which Mr. Reid Moir reports that a certain number are undoubtedly of high antiquity, ranging from eolithic to Clactonian I. Lieut. K. R. W. Todd enumerates stone age sites, mostly palæolithic, from which he has obtained a considerable number of implements, in the neighbourhood of Bombay; and Prof. A. Barnes discusses the mode of prehension of some forms of upper palæolithic implements. The important work of exploration at Grimes' Graves has been continued and Mr. Leslie Armstrong reports on the examination of five pits, one still unfinished, since the date of the last report in 1926. Two communications deal with different aspects of related problems. Of these, one by Mr. Stuart Piggott and Prof. Gordon Childe describes and discusses the affinities of neolithic pottery from Larne, now in the Ashmolean Museum. The authors conclude that in decoration this pottery is a reflex of the current round the north of the British Isles that is supposed to have brought the passage-grave idea to Denmark, while in form it is the most distinctively Iberian in the whole Windmill industry. In the second communication, Mr. J. G. D. Clark examines the distribution of the curved flint sickle blade in Britain, and deriving it from the Nordic culture area, thinks it is to be associated with the Peterborough pottery folk, while it is probable that the Windmill Hill people used a composite sickle. In addition to other communications, there are some useful notes and references.

Barrages on the Niger

One of the most important irrigation schemes in the African Sudan is being carried out in the Upper Senegal district of French West Africa, where the project is to irrigate the Macina district from the flood waters of the Niger. A few details are given in *Terre Air Mer* for February. At Bamako the Sotuba barrage, 1,340 yards long, irrigates about 15,000 acres on the right bank. The chief barrage, however, is in course of construction below Segu about 200 miles farther downstream at Diamarabougu. This will be about 1,300 yards long and will feed a number of canals on the left of the river. Some of these are already cut and embanked. A navigation canal with locks will be built round this barrage. It is estimated that this irrigation scheme will eventually allow the population of the area affected to be increased five-fold with crops of rice, cotton, forage plants and live-stock.

Sir Patrick Geddes

A supplement issued with the recent number of the *Sociological Review* (vol. 24, No. 3) consists of tributes to the late Sir Patrick Geddes by friends, former pupils and fellow-workers, in which his many-sided genius, his fertility in ideas and his gift for inspiring enthusiasm in others are commemorated. Sir D. M. Stevenson, Lord Provost of Glasgow, writes of "the Social Reformer"; Mr. Edward McGegan, writing from the Outlook Tower, Edinburgh, with which the name of Geddes will always be associated, speaks of him as a man of action; Lord Sandwich records his part in the saving and re-erection of Crosby Hall; Dr. R. S. Buist tells of his work at University College, Dundee; while intimate views of his enthusiasms, with which he fired others, are given in accounts of his schemes for forming a university students' quarter in London, of his work in town planning in India and in Palestine and his Collège des Ecossais at Montpellier, by writers who were closely associated with him in these undertakings.

Moles Storing Worms

Referring to notes in our Calendar of Nature Topics of Feb. 25, Mr. Lionel E. Adams, Wheatley, Shide Cross, Newport, I.O.W., who contributed a valuable paper entitled "Observations on a Captive Mole" to the *Proceedings of the Manchester Literary and Philosophical Society* of May 31, 1906, and later, an illustrated article entitled "Moles and Molehills" to Nature of March 10, 1910, p. 37, writes: "A farmer on whose land I was trapping moles, informed me that while digging out a 'fortress' he came across a mass of dead worms in the nest cavity close to the nest. He described the quantity as 'three spadefuls'. I have frequently watched captive moles bury worms when their hunger was satisfied. The mole would bite the worm with quick bites along its whole length and then cram it into the earth and scratch the earth over it with his fore paws."

Australian Entomology

Amongst many valuable references to papers in all branches of science, *Australian Science Abstracts* (No. 4, Nov. 1932) records a "Bibliography of Australian Entomology, 1775–1930", published by the Royal Zoological Society of New South Wales (1932, pp. 1–380). In the list of papers and works touching on Australian insects during that period are references to scientific expeditions which have visited Australia and information concerning authors, collectors and collections. Invaluable to entomologists, the work will be found useful also by zoologists and botanists. An index classifies papers written on various orders of insects, as well as papers on economic, medical and veterinary entomology, and on Australian fossil insects.

The Faraday House Journal

The part played by the Faraday House Electrical Engineering College in providing Great Britain with electrical engineers has been a very important one. Its old students are found occupying many of the highest positions in the electrical industry, and the recent issue of the *Faraday House Journal* states that more than 2,000 students have passed through the College. The virtual founder of the College was Robert Hammond, who in 1882 opened the Hammond Electrical Engineering College. In one of the notes in the *Journal* reference is made to the attempt to light Cockermouth with electricity in 1881, the opening function being attended by Hammond. That same year Godalming was lighted by electricity, but whereas this proved successful the scheme at Cockermouth failed. The *West Cumberland Times*, however, looking ahead, said that electricity would revolutionise the world, that the maturing of fruits and vegetables would be speeded up by its use and that the dynamo would be as common on the farm as the threshing machine.

The Ray Society

At the annual general meeting of the Ray Society, held on March 22, the following officers were re-elected: *President*, Sir Sidney Harmer; *Treasurer*, Sir David Prain; *Secretary*, Dr. W. T. Calman.

Mr. Charles Oldham was elected a vice-president and Mr. D. J. Scourfield, Mr. J. Spedan Lewis and Mr. David Bryce were elected new members of council. It was announced that the third volume of Dr. Gurney's "British Freshwater Copepoda" is in the press, and will form the issue for the current year. For future issue, in addition to the second volume of Prof. Stephenson's "British Sea Anemones", the Council has provisionally accepted works on British Neuroptera by Mr. F. J. Killington, on British Psocoptera by Mr. J. V. Pearman, and on British Freshwater Planarians by Mr. Philip Ullyott, all of which are in active preparation.

Announcements

At the annual general meeting of the Institute of Metals, the following officers were elected for the year 1933–34: *President*: Sir Henry Fowler; *Vice-Presidents*: Prof. C. H. Desch and Prof. R. S. Hutton; *Members of Council*: Eng. Vice-Admiral Sir Robert Dixon, Mr. Wesley Lambert, Mr. H. C. Lancaster, Mr. A. H. Mundey, Mr. A. J. G. Smout, Mr. F. Tomlinson. The silver Jubilee meeting of the Institute will be held in Birmingham on September 18–21. It was in Birmingham that the first general meeting of the Institute was held in the autumn of 1908, under the presidency of the late Sir William White.

The Institute of Physics announces that the B.O.I.M.A. Prize for the best paper published in the *Journal of Scientific Instruments* during the year 1932 has been awarded to Mr. E. Lancaster-Jones, of the Science Museum, for his paper on "The Principles and Practice of the Gravity Gradiometer", and the Institute of Physics prize for the best contribution to the Laboratory and Workshop Notes in the *Journal* has been awarded to Dr. J. L. Miller and Mr. J. E. L. Robinson of Messrs. Ferranti, Ltd., for their joint note entitled "A Three-Dimensional Adjustment of an Electrode in Vacuo".

A special exhibition in commemoration of the death, on April 22, 1833, of Richard Trevithick, the great advocate of the high-pressure steam engine and the 'father' of the railway locomotive, is being held in the Main Hall of the Science Museum, South Kensington, from March 31 until the end of June. The exhibition includes examples of engines, etc., designed by him as well as numerous other objects relating to him and his work.

The fourth annual exhibition of television and photoelectric apparatus arranged by the Television Society will be held at the Imperial College of Science and Technology, South Kensington, S.W.7 on April 5 at 6–9 p.m. and April 6 at 3–9 p.m. The exhibition catalogue (price 6*d*., or post paid, 7*d*.) can be obtained on about April 3 from the exhibition secretary, Mr. W. G. W. Mitchell, "Lynton", Newbury, Berks. Further information and cards of admission can be obtained from the honorary business secretary of the Television Society, Mr. J. J. Denton, 25, Lisburne Road, Hampstead, N.W.3.

We have received from British Glues and Chemicals Ltd., Imperial House, 15, 17, 19 Kingsway, London, W.C.2, a pamphlet containing particulars of an international competition organised with the object of promoting interest and research in the development of the uses of bone glue. Provision has been made for prizes to the total value of 20,000 Swiss francs and a further sum of 10,000 Swiss francs is held in reserve to be employed in special cases set out in the rules. A copy of the pamphlet containing the rules and any further information may be obtained at the above address (Department I/S).

In the review of Dr. W. N. Bond's "Numerical Examples in Physics" in Nature of March 4, the reviewer suggested that it was a slip on the part of the author to express the mass of the sun as 1·47 kilometres, and to specify a piece of glass as having a refractive index of 1·961. Lord Holden has written to point out that the former is a statement in terms of units that Eddington has found it convenient to use. It may therefore be regarded as correct but rather cryptic. As regards the second statement, glass has been made of such a large refractive index as is given in the question, though it is not very satisfactory in use, turning yellow with age. The high value of the refractive index was intended by Dr. Bond to add point to the numerical example.

Applications are invited for the following appointments, on or before the dates mentioned:—Three *junior assistants in the Chief Engineer's Department* of the Metropolitan Water Board—The Chief Engineer, Offices of the Board, 173, Rosebery Avenue, E.C.1 (April 6). A temporary principal technical assistant in the Shellfish Services Staff and an assistant naturalist in the Fisheries Department of the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S.W.1 (April 10). Examiners in botany and mathematics in the matriculation and General School examination of the University of London—The Secretary to the Matriculation and School Examination's Council, University of London, South Kensington, S.W.7 (April 18). A professor of physiology in the University of Sheffield—The Registrar (April 20). A senior pathologist in the Department of Preventive Medicine of the University of Bristol—The Secretary (April 20). A scientific assistant in the Imperial Bureau of Plant Genetics: Herbage Plants, Agricultural Buildings, Aberystwyth, Wales—The Director (April 21). A demonstrator in the Department of Zoology at Bedford College for Women, Regent's Park, N.W.1—The Secretary (April 29). An inspector of installations (heating, ventilating, electrical, sanitary, etc.) for the new buildings of the Société des Nations—Le Bureau du Personnel, Secrétariat Société des Nations, Geneva (April 30). A lecturer in helminthology in the Department of Zoology and the Royal (Dick) Veterinary College (University of Edinburgh)—The Secretary of the University (May 24).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Protective Inoculation against a Plant Virus

The *X* virus of the potato, first described by Kenneth Smith[1], is capable of considerable variation in virulence, as shown by its clinical expression on several of the Solanaceæ. If tobacco plants be inoculated from the potato and the virus maintained by *passage* over a long period, the clinical expression may pass from a more or less mild mottling of pale and dark green, to a stage in which the pale areas are bright yellow, ending in one in which the lesions become extensively necrotic. Inoculation with the virus in this latter stage causes young tobacco plants to remain in a dwarfed and crippled condition.

Some four months ago, a series of experiments was instituted in which segments of about 2 mm. diameter were punched out of the green and yellow areas respectively of a leaf of a somewhat severely affected *X*-infected tobacco plant of the White Burley variety, and inoculated by needle into young and healthy seedlings of the same variety. It was at once evident that two distinct clinical conditions had ensued. From the green areas there resulted an exceedingly mild disease we may designate the *G* type of *X*, from the yellow areas a severe disease with large bright yellow patches on a pale green background accompanied by dwarfing; we may designate this the *L* type of *X*. So far, no further development of virulence has occurred in this type, although the *G* strain has, by selective sub-culture, been reduced to one giving an almost imperceptible reaction. Mixing the *G* and *L* tissue extracts in varying proportions *in vitro*, and inoculating tobacco seedlings with the same, has shown that a mixture of 1 *L* : 9 *G* produces a preponderantly *G* reaction, whilst mixtures with less of the *G* element call forth a reaction like that of *L*. Although plants infected with a 1 *L* : 9 *G*, or a 1 *L* : 19 *G* mixture behave, in general, like *G* infections, yet small areas of bright yellow, such as is common in the *L* type, do appear scattered on the otherwise almost normal green leaf. Sub-cultures from such yellow and green areas respectively, in these mixed infections, reproduce the original *L* and *G* types. There has been mixture of the two strains, not neutralisation of one strain by the other.

If tobacco plants inoculated with the mildest type of the *G* form of the *X* virus—no matter whether the ensuing reaction is definite enough to be recognised as a mottle, or so slight as merely to arouse a suspicion of its presence—are re-inoculated after nine days, either with the *L* strain or the most virulent necrotic type of *X* we possess, no further reaction ensues. Such plants retain their mild, almost imperceptible, *G* type of reaction, and present a solid immunity against the further attack of the *X* virus however virulent it may be. Later experiments have shown that this protection against the virulent strains of *X* is developed on the fifth day after the preliminary inoculation, and some four to five days before any systemic response to *G* is apparent. When from such doubly inoculated plants sub-cultures are made, only the *G* type of the *X* virus is obtained; the secondarily inoculated and severer type has failed to gain an entry. It would appear that once the plant cell has formed a symbiotic union with the non-virulent form, it has no capacity to enter into relations with any other virus elements of the same generic type.

The reactions recorded above have been repeated on *Datura strammonium*: in this species both the *L* and the necrotic forms of *X* produce a deadly effect. It is, however, only necessary to give the *Datura* plants a preliminary dose of the *G* form of the *X* virus, which induces but a mild mottle with little or no hindrance to growth, and subsequent inoculation a week later with the most severe *X* virus is without effect.

The protection afforded by the *G* strain holds good also for Miss Hamilton's[2] Hy IV, an *X* type of virus discovered in field crops of *Hyoscyamus*, but it is powerless against the *Y* potato virus of Kenneth Smith[1], as well as against that of the common tobacco mosaic, Johnson's No. 1.

The green 'veinbanding' islets, a late development on the leaves of tobaccos infected with the *Y* virus, have been examined by the same methods but with different results. Here neither evidence of a mild or symptomless *G* form, nor that of any adequate protective mechanism, has as yet been found. Indeed the central portions of such green islets appear to be free of virus. A similar condition was shown by Storey and McClean[3] to exist in streak-infected maize. How such green areas, surrounded by a solid mass of heavily infected cells, retain their freedom from virus, is a problem distinct from that of the corresponding areas in the *X*-infected plant.

Within the limits of this communication it is not possible to do more than refer very briefly to the results of others. McKinney[4] differentiated green and yellow strains in rosette disease of wheat, as has been done here with the *X* virus. Both Price[5] and Thung[6] have recorded observations which suggest a similar type of immunity. The phenomenon here described is, however, distinct from theirs, inasmuch as the protection afforded is achieved by a preliminary inoculation of a virus with an almost subliminal virulence, with the result that neither protective nor subsequent inoculation has any appreciable effect on the health of the plant.

Experimental Rickets as a Phosphorus Deficiency Disease

Although both prophylactic and curative technique against rickets is now highly developed, the pathogenesis of the disease is still far from being adequately understood. Recent experimental findings—some having already been published[1], others to be published shortly—are briefly summarised here since they afford, it would seem, strong support for the view that, whilst other factors play a part, and it would be idle to endeavour to dissociate phosphorus from calcium metabolism, yet nevertheless *a chronic defect of phosphorus uptake from the diet* is the most important single factor in the production of experimental rickets in rats. This is very probably true in a large proportion of cases of human rickets also, vitamin D being of importance in the rat or human dietary only in so far as its presence enables the organism to increase the net intestinal absorption of phosphorus from the food. Our findings also throw a little light, it is believed, on the part played by the bone enzyme in this disease.

(*a*) We have found that on a normal stock diet, (Bills's[2]) with or without extra vitamin D in the form of irradiated ergosterol or cod liver oil, very severe rickets, demonstrated by X-ray photographs, by the histological appearance of sections of the long bones and by bone ash and plasma phosphate analyses, may be brought about in growing rats by the simple expedient of adding 0·5 per cent of *beryllium carbonate* to this normal diet. With smaller quantities of the carbonate down to 0·1 per cent or even less, a milder rickets may be produced, amenable in some degree to therapy with the usual antirachitic agents. The addition of an equivalent quantity of beryllium *phosphate* to the Bills's diet has no such effect, and the rats continue to grow normally.

Beryllium is peculiar in forming a phosphate which is highly insoluble even in fairly acid solutions (*p*H4 or less). Its rachitogenic effect is almost certainly bound up with this property, the beryllium dissolved in the gastric juice precipitating quantitatively in the intestine with any free phosphate found there, whether derived from the food or from the intestinal secretions, and removing it in the insoluble form in the fæces.

The possibility has not been overlooked that beryllium may be taken up from the food, and have a specific toxic effect on the growing bone. That this is probably not the case is indicated not only by the experiments just mentioned, in which beryllium *phosphate* added to the diet permitted of strictly normal growth, but also by the absence, histologically, of any evidence of toxic disturbance of the bone or cartilage cells. Moreover, qualitative chemical analysis of the ash of the bones and other tissues of the experimental animals has so far failed to reveal any recognisable quantities of beryllium, using a method sensitive to the presence of 1 part of beryllium in 100 parts of calcium.

(*b*) In the 'beryllium rickets' described above, and also in rickets produced in rats by the rachitogenic diet McCollum 3143 or Steenbock 2965, we have found that in addition to a very low plasma inorganic phosphate (in beryllium rickets values so low as 0·4 mgm. phosphorus per 100 c.c. plasma have been found), there is also a marked diminution in the *phosphoric ester content of the red blood cells*. Assuming the correctness of Robison's theory[3] of the function of the bone phosphatase in the deposition of bone salts, and that the phosphoric esters of the red cells form an important substrate for the activity of this enzyme, it would appear that rickets is explicable as the result, on the physico-chemical mechanism of bone deposition, of a two-fold handicap, first the low inorganic phosphate in the plasma, and secondly the low phosphoric ester content of the circulating blood. If vitamin D be added to the McCollum or the Steenbock diet of such rachitic animals, during the time the rickets is disappearing the phosphoric ester content of the red cells is increasing towards normal.

The above findings fit in very satisfactorily with the recent work of Shohl and collaborators[4] on rat rickets, of Theiler and Green[5] on the production of rickets and osteomalacia in herbivorous animals, and of Bodansky and his co-workers[6] on human rickets. The accumulated evidence may now be sufficient to support the corollary that the most important, if not the essential, effect of vitamin D in physiological quantities is to increase directly the intestinal absorption of phosphate (which normally implies increased uptake of calcium also) from the diet. It seems likely that, in the human, the functional efficiency of the intestine in the taking up of phosphate may vary markedly from one normal individual to another, the diet being the same. In certain stubborn cases of infantile rickets or adult rickets (osteomalacia) we may be dealing, essentially, with individuals in whom, as the result of an inborn or acquired functional defect of the intestine, this ability to take up phosphate from the contents of the gut is abnormally low, rather than with individuals in whom there is a deep-seated metabolic error or an essential deficiency in the process of bone formation itself. Their cure (if the intestinal absorptive mechanism had not degenerated too far) by the addition of generous quantities of vitamin D to the diet would then be explicable by the action of the vitamin not *directly* on the deposition of bone, but indirectly in stimulating phosphate uptake through the defective intestinal wall, a suggestion which, though not new, has hitherto been somewhat lacking in experimental support.

Estimation and Distribution of Ascorbic Acid (Vitamin C) and Glutathione in Animal Tissues

MOST of the recorded measurements of the reduced glutathione content of tissues have been made by Tunnicliffe's method of titration with iodine on the assumption that the trichloracetic extracts of tissue contain little else but glutathione capable of reducing iodine in acid solution. A method depending upon a different principle was introduced by Mason, who found that the reduced glutathione content of liver, kidney and yeast extracts determined by titration against iodine is 120–200 per cent of the true value. His method has however been neglected, and the iodine method has been used almost exclusively. Recently, Bierich has evolved a third method for the estimation of reduced glutathione and has also obtained values much lower than those obtained by iodine titration. Ever since the discovery of ascorbic acid, it has been evident (as is mentioned by these workers) that where ascorbic acid occurs in the tissues, it will be estimated as glutathione in the iodine titration ; but it has been assumed without any evidence that ascorbic acid occurs only in traces except in the suprarenal cortex.

Using the indophenol titration method of Tillmans as modified in this laboratory for the estimation of ascorbic acid, we have found that ascorbic acid occurs in a number of organs in amounts comparable with that of glutathione, and that in organs other than the suprarenal cortex, up to 40 per cent of the iodine titre ('glutathione') may be accounted for by the ascorbic acid. Figures are given for blood, voluntary muscle, liver, kidney and the lens of the eye in the accompanying table. In view of this finding, data relating to the glutathione content of tissues, and factors influencing it, will require a thorough re-examination.

Tissue	Ascorbic acid (mgm. per gm.)	*N*/100 I_2 required for ascorbic acid present (c.c.)	Total N/100 I_2 required per gm. tissue (c.c.)	Per cent of I_2 titre due to ascorbic acid
Rat blood	<0·02	<0·023	0·197	<12
„ muscle	0·06	0·068	0·232	29
„ liver	0·15	0·188	1·14	16
„ kidney	0·22	0·25	0·910	27
Sheep liver	0·45	0·512	1·51	34
„ eye lens	0·46	0·52	1·64	32
Pig liver	0·38	0·432	1·44	30
Rabbit liver	0·40	0·455	1·33	34
„ kidney	0·25	0·285	0·655	43
Guinea pig liver, scorbutic	0·09	0·102	1·16	9
„ „ „ normal	0·30	0·34	0·97	35
Ox suprarenal cortex ..	1·62	1·85	2·40	77

From the data collected in the table, it will be seen that those tissues known to be rich in glutathione also have a high ascorbic acid content, and this coincident occurrence of the two substances has led us to formulate the working hypothesis that ascorbic acid and glutathione may be two linked factors in one system of oxidation in the animal cell. This has already led to the discovery of a thermolabile agent which is a catalyst for the dehydrogenation of ascorbic acid.

It must be borne in mind that although glutathione does not reduce 2–6 dichlorphenolindophenol under the conditions employed, there may be other unsuspected substances in the tissue extracts which will reduce the reagent, and therefore will be included in the estimation as ascorbic acid, causing too high a figure to be obtained. Fortunately, the ascorbic acid content as determined by the titration method can be checked by measuring the antiscorbutic activity of the tissue, and experiments with this object are already in progress.

Action of Proteolytic Enzymes on the Oxytocic Principle of the Pituitary Gland

FOR more than a year we have been engaged in a study of the inactivation by enzymes of purified preparations[1] of the oxytocic principle of the pituitary gland. The stimulating action of the hormone on smooth muscle is slowly destroyed by aminopolypeptidase preparations from English brewers' yeast, and is rapidly destroyed by dipeptidase and proteinase preparations from the same source. Preparations of dipeptidase and aminopolypeptidase, with which Dr. Grassmann of Munich kindly presented us, also inactivated the hormone. None of the enzymes mentioned above is responsible for this inactivation. It is apparently due to an additional enzyme, present in these preparations, which has a *p*H optimum at 7·4.

Recently Freudenberg, Weiss and Eyer[2] stated that "die Wirkung der Substanz [the oxytocic hormone] von Pepsin und Erepsin nicht verändert, von Trypsin und Papain (auch wenn dieses nicht aktiviert ist) aber zerstört wird. Das Hormon ist entweder hochmolekular oder an einem hochmolekularen Träger der Eiweissgruppe gebunden. Offenbar gehört es dem Typus des Insulins an". We concur that papain preparations destroy the hormone rapidly, even more rapidly than do dipeptidase preparations, but the *p*H-optimum and *p*H-activity curve of the enzyme causing this destruction are the same as those of the yeast enzyme mentioned above. It is improbable, therefore, that the destruction of the oxytocic hormone is caused by a papainase, and we suggest that it is due to the presence in the papain preparations of an enzyme identical with, or similar to, the enzyme which we have detected in yeast.

Our experiments with the yeast enzyme and papain preparations will shortly be published *in extenso*. Experiments are in progress to identify the enzyme which destroys the oxytocic hormone, and we have been occupied for some time in investigating the constitution of the hormone by studying its behaviour with other enzymes and with chemical reagents. The results of an investigation of the action of nitrous acid and other reagents on the hormone have already been published[3].

Predissociation and Pressure Effects in the Band Spectrum of Aluminium Hydride

BY the aid of graphical methods[1], we have constructed the potential curves $V_J(r)$ for different rotational states of $^1\Pi$ in aluminium hydride. From estimations on the line width of the diffuse lines in the $^1\Pi \rightarrow {}^1\Sigma$ band system, we were able to extend our constructions to wide nuclear spacing ($r \sim 3 \times 10^{-8}$ cm.) as shown in Fig. 1. Reproducing the curve $V_0(r)$ for $J = 0$ $\left[V_J(r) = V_0(r) + \frac{h}{8\pi^2\mu r^2} J(J+1)\right]$ we found, that even now a potential barrier remains in $^1\Pi$, the height of which is ~ 400 cm.$^{-1}$, as related to the limit of dissociation. This result appears somewhat surprising, as in the few cases hitherto investigated (hydrogen, mercury hydride, etc.) a smooth approach of the potential curves to the limit of dissociation has been assumed. We are not in the position to distinguish between the alternatives, whether this barrier is a feature of the $^1\Pi$-state itself or produced by the intersection of some unknown and repulsive $^1\Pi^*$-state, as suggested in Fig. 1. In the latter case, the actual $^1\Pi$-curve should be correlated to some excited state in the Al atom as already suggested by Kronig[3], although for other reasons. In any event, by this construction the level scheme of AlH has been related to that of the Al atom, the position of the level $v = 0$, $J = 0$ in $^1\Pi$ situated 1400 ± 50 cm.$^{-1}$ below the limit of dissociation. Incidentally, it may be mentioned that some interesting cases of perturbations and predissociations in the excited $^1\Sigma'$ and $^1\Sigma''$ states[4] are readily explained hereby.

The transparency of the potential barrier to the de Broglie waves is a well-known effect[3], which has been applied especially to the problems of the disintegration of atomic nuclei and molecules. Generally, the effect of transparency is given by an expression $\frac{\omega}{\pi} e^{-\beta_J}$, where $\beta_J = \frac{4\pi}{h} \int_{r_1}^{r_2} \sqrt{2\mu\,[V_J\,(r) - E]}\,dr$. In the special case here considered, the life of molecules in $^1\Pi$ is thereby reduced from 10^{-8} sec. to $\sim 10^{-13}$ sec. in the most excited rotational states observed. In addition, we wish to point out a reciprocal effect, which comes into play when we consider the problem of molecular formation. In cases of resonance between the system of free atoms and the molecule formed, the probability of capture per collision is determined by an expression $\sim e^{+\beta_J}$. Apparently, this resonance effect plays an important rôle, influencing the processes of exchange between atomic and molecular states [$\mathrm{Al} + \mathrm{H} \rightarrow \mathrm{AlH}$] in favour of molecular formation. To speak more figuratively, the barrier acts as if perforated by a system (J, v) of narrow channels, by which the molecular formation and dissociation takes place.

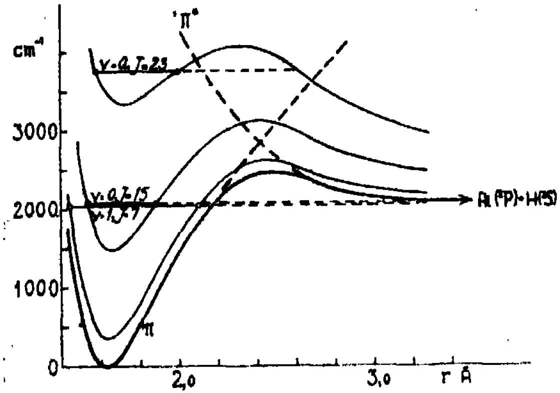

FIG. 1.

Applying these considerations to the case of AlH, we expect an excess in the number of molecules of those rotational levels which are situated close above the limit of dissociation in $^1\Pi$, an effect clear enough to be distinguished from those determined by the thermal and electronic activation of the molecules. From a close examination of the intensity distribution in the bands of $^1\Pi \rightarrow {}^1\Sigma$, emitted by an aluminium arc burning in pure hydrogen of one atmosphere pressure, we found that the lines originating from the rotational levels $J = 15$ in $v = 0$ and $J = 7$ in $v = 1$ exhibit distinct peaks on the smooth curves of intensity, given by the expression $ie^{-\frac{E}{kT}}$. It must be emphasised that these lines still belong to the type of sharp band lines, the disintegration of the molecule in the initial state being protected by an almost impenetrable potential barrier.

At low pressure (~ 10 mm. mercury) in the arc, the exciting conditions are mainly due to electronic activation of the molecules. In the states of predissociation, by increasing pressure, this effect is superposed by the effect of molecular formation. The sensible influence observed[4] of the hydrogen pressure on the intensity of the diffuse lines may be *interpreted by the aid of the mechanism of resonance*, suggested above. Although somewhat hampered by the damping factor $e^{2\beta}$, the resonance process must be largely favoured by an increasing number of molecules within the radius of interaction of the individual Al + H process.

Details regarding the investigation will be given later.

New Experimental Evidence in the Sulphur-Hydrogen Reaction

BODENSTEIN[1] studied this reaction in sealed bulbs containing excess of sulphur, and found a temperature coefficient of 1·34 between 234° and 283°, and 1·77 between 310° and 356°. His work was criticised, by Norrish and Rideal[2], as possibly vitiated by the hydrogen sulphide liberated on the solidification of the residual sulphur, and as leaving uncertain, in view of the variable temperature coefficient, the part played by the walls of the bulbs. These workers employed a dynamic method, and showed that the logarithms of the total reaction velocity—always, however, measured in the presence of nitrogen—when plotted against absolute temperature yielded a curved line. The differences in the velocities obtained, using hydrogen at partial pressures of 0·810 atm. and 0·304 atm., respectively, when suitably plotted gave a straight line which was interpreted as belonging to the gaseous reaction alone, since the surface reaction, common to each series, was assumed, and reasonably so, to be independent of pressure. The velocity of the composite reaction was also shown experimentally to be increased by increasing the glass surface, to which it was stated to be proportional; and to be independent of the amount of sulphur present. Knowing the contribution of the gaseous reaction, data for the surface were deduced, and thus the temperature coefficient of each reaction was obtained: homogeneous 2·19, heterogeneous 1·48.

The assumption, fundamental to their deductions, made by Norrish and Rideal, that nitrogen is without effect on the velocity of the formation of hydrogen sulphide, has not been borne out by our re-examination of the problem. Actually, nitrogen definitely increases the velocity of the gaseous reaction over practically the whole of the temperature range under consideration. Furthermore, we have been unable to obtain any evidence of the heterogeneous reaction, described by them as taking place on the glass surface of the vessels. A heterogeneous reaction of some magnitude has, however, been observed, but it is confined to the surface of the sulphur, its velocity being proportional to the area thereof.

At 760 mm., in pure hydrogen, when precautions were taken to keep a uniform pool of sulphur in the reaction vessel, the dynamic method, in our hands, gave a practically straight log d [H_2S]/dt against $1/T$ plot between 265° and 350° The velocities were unaffected by an increase in the surface/volume ratio of 500 per cent, but were appreciably altered by changes in the area of liquid sulphur; in the latter case, within certain limits, the temperature coefficient of the total reaction was not sensibly changed, provided the particular areas were kept constant throughout the temperature range. The introduction of nitrogen resulted in a curve, similar in form, and close in actual position, to that of Norrish and Rideal, and the velocities were somewhat higher than was warranted by the partial pressure of hydrogen employed.

A study of the gas reaction was made, statically, in bulbs, wherein the amount of sulphur was always more than twenty times that converted to the hydride, but was, nevertheless, insufficient to allow of any liquid being present. The surface/volume ratio and the pressure of hydrogen were varied, and the results showed that the velocity of hydrogen sulphide formation was: (1) proportional to the concentration of hydrogen; (2) proportional to the square root of the concentration of sulphur; (3) independent of the area of the glass surface.

The plot of log $d[H_2S]dt$ against $1/T$ was perfectly straight, and gave a temperature coefficient of 1·94. With the same partial pressure of hydrogen, in the presence of nitrogen, log d [H_2S]dt against $1/T$ was decidedly curved, and the velocities were appreciably greater than with pure hydrogen. The difference, brought about by the nitrogen, points to a chain mechanism, and the investigation is proceeding with the substitution of helium for nitrogen, and with the limitation of the space for chain formation. The gaseous reaction proceeds in accordance with the equation,

$$d\,[H_2S]/dt = K\,[H_2] \times \sqrt{[S]}.$$

Two or three forms of chain mechanism suggest themselves, but we hesitate to differentiate between these in the absence of other data which are at present being sought.

By a modification of the shapes of the bulbs, whereby three pools of liquid sulphur, of different sizes, were exposed to the action of hydrogen, the composite reaction, in the presence of known areas of sulphur, was investigated. The velocity of the surface reaction was computed by deducting that of the homogeneous one from the composite figure, and its temperature coefficient was estimated from the results obtained. The reaction at the surface of liquid sulphur proved to be: (1) proportional to the area of the liquid exposed; (2) proportional to the pressure of hydrogen. It gave a straight log d [H_2S]/dt against $1/T$ plot, from which a temperature coefficient of 1·85 was calculated. The surface reaction proceeds in accordance with the equation,

$$d\,[H_2S]/dt = K \times \text{area of liquid sulphur} \times [H_2].$$

Although Bodenstein failed to recognise the composite nature of the reaction between hydrogen and sulphur, first suggested by Norrish and Rideal, he evidently believed it to have the characteristics of the gaseous reaction here described, in spite of the fact that his analytical results did not entirely confirm this view. His approximate methods also obscured the effect of the heterogeneous reaction occurring at the sulphur surface and prevented its detection.

Variation Problems for a Symmetrical Region

IN a review in NATURE[1] it is stated that the equation of conduction of heat can be regarded only as a *limiting* case of an equation arising in the calculus of variations. A successful attempt has been made, however, to derive the equation directly from a variation problem of an unusual type.

It is found that if we write

$$u = F\,(x, t),\ v = F\,(x, -t)$$

and integrate

$$\frac{\delta u}{\delta x}\,\frac{\delta v}{\delta x} \times v\,\frac{\delta u}{\delta t}$$

over a region bounded by the lines $x = \pm a, t = \pm b$, requiring F to be zero on the boundary, the variation of the resulting integral I gives rise to the differential equation

$$\frac{\delta^2 u}{\delta x^2} = \frac{\delta u}{\delta t}.$$

A physical meaning for I has not yet been found.

A variation problem for a symmetrical domain usually gives rise to a functional equation such as $F''\,(t) = n^2\,F\,(-t)$. A solution $F\,(t) = A \cosh\,(nt) - B \sin\,(nt)$ of this equation may be found by splitting $F\,(t)$ into its even and odd parts, a device that is often useful.

H. BATEMAN.

Pasadena, California.

---

[1] NATURE, **129**, 850, June 11, 1932.

IF, in Prof. Bateman's example, we take

$$F\,(x,\ t) + F\,(x, -t) = 2\,\varphi\,(x, t),$$
$$F\,(x,\ t) - F\,(x, -t) = 2\,\psi\,(x, t),$$

then φ and ψ may be regarded as independent of each other, and the variational equations are

$$\frac{\delta\varphi}{\delta x^2} = \frac{\delta\psi}{\delta t}, \qquad \frac{\delta^2\psi}{\delta x^2} = \frac{\delta\varphi}{\delta t}.$$

It is true that the equation $\frac{\delta^2 u}{\delta x^2} = \frac{\delta u}{\delta t}$ can be derived by adding these two equations, but it represents only a *part* of the variational system: *the whole* set consists of the above two equations, which when we eliminate ψ give

$$\frac{\delta^4\varphi}{\delta x^4} = \frac{\delta^2\varphi}{\delta t^2},$$

and I regard this as the true differential equation arising in Prof. Bateman's problem.

E. T. WHITTAKER.

Fluorescence of Pure Salts of the Rare Earths

Investigating the connexion between the emission spectra in colourless materials[1] and the absorption spectra of the ions of the rare earths[2] we have found that the pure salts of the rare earths can also exhibit a fluorescence of a surprising brightness. Up to the present, this fact was still very doubtful[3]. Under excitation with violet and ultra-violet light, europium sulphate in particular shows a brilliant red fluorescence. Terbium sulphate fluoresces also very strongly with a pale greenish colour. The luminosity of the sulphates of samarium and dysprosium is weaker. Our samples of the sulphates of holmium and erbium showed no perceptible emission. The spectra emitted are very sharp, especially at lower temperatures.

Conclusive proof that the emission is to be ascribed to the pure salts and not to any impurities is given by comparing these spectra with the phosphorescence spectra, when the same ion (in a small amount of about 0·1 per cent) is embedded in a colourless salt by heating. The agreement between the particular groups in the spectra of a given ion shows at the first glance[4] that the fluorescence is due to the ion of the pure salt. Therefore this emission is of the same type as that of the uranyl salts and also the duration of the fluorescence is of the same order.

New Evidence for the Positive Electron

The experiments of Anderson[1] and of Blackett and Occhialini[2] on the effects produced in an expansion chamber by the penetrating radiation strongly suggest the existence of positive electrons—particles of about the same mass as an electron but carrying a positive charge.

Some observations of the effects produced by the passage of neutrons through matter, and the experiments of Curie and Joliot[3] in which they observed retrograde electron tracks in an expansion chamber, led us to consider the possibility that positive electrons might be produced in the interaction of neutrons and matter, and we have recently obtained evidence which can be interpreted in this way.

A capsule containing a polonium source and a piece of beryllium was placed close to the wall of an expansion chamber. On the inside of the wall was fixed a target of lead about 2·5 cm. square and 2 mm. thick. This lead target was thus exposed to the action of the radiation, consisting of γ-rays and neutrons, emitted from the beryllium. Expansion photographs were taken by means of a stereoscopic pair of cameras. A magnetic field was applied during the expansion, its magnitude being usually about 800 gauss.

Most of the tracks recorded in the photographs were, from the sense of their curvature, clearly due to negative electrons, but many examples were found of tracks which had one end in or near the lead target and showed a curvature in the opposite sense. Either these were due to particles carrying a positive charge or they were due to negative electrons ejected in remote parts of the chamber and bent by the magnetic field so as to end on the lead target. Statistical examination of the results supports the view that the tracks began in the target and therefore carried a positive charge.

Strong evidence for this hypothesis was acquired by placing a metal plate across the expansion chamber so as to intercept the paths of the particles. Only a few good photographs have so far been obtained in which a positively curved track passes through the plate and remains in focus throughout its path, but these leave no doubt that the particles had their origin in or near the lead target and were therefore positively charged. In one case the track had a curvature on the target side of the plate, a sheet of copper 0·25 mm. thick, corresponding to a value of $H\rho$ of 12,700; on the other side the curvature gave a value $H\rho = 10{,}000$. This indicates that the particle travelled from the target through the copper plate, losing a certain amount of energy in the plate. The change in the value of $H\rho$ in passing through the copper is roughly the same as for a negative electron under similar conditions. The ionising power of the particle is also about the same as that for the negative electron. These observations are consistent with the assumption that the mass and magnitude of the charge of the positive particle are the same as for the negative electron.

The manner in which these positive electrons are produced is not yet clear, nor whether they arise from the action of the neutron emitted by the beryllium or from the action of the accompanying γ-radiation. It is hoped that further experiments now in progress will decide these questions.

Our thanks are due to Mr. Gilbert for his help in the experiments.

Summer Thunderstorms

The annual record of thunderstorms occurring in the six summer months is being continued during 1933.

A note of the place, date and time of the occurrence of thunder, lightning or hail, in any part of the British Isles, between April 1 and September 30, with the direction in which the lightning was seen, especially at night, will be extremely useful. In the case of actual thunderstorms, information as to the time of first observation of thunder or lightning, time of commencement of very heavy rain or hail, or approximate time of nearest approach of storm, and approximate time of final observation of thunder or lightning will be valuable.

It is essential that the position from which the observation is made should be specified, and that the standard of time used should be stated. More data are particularly required from rural and moorland districts and from thinly populated areas generally.

Research Items

Iron-working in the Bahr el Ghazal. Mr. T. C. Crawhall in *Man* for March describes the processes of iron-working and forging as practised by the Jur of the Sudanese province of Bahr el Ghazal, which are illustrated by some exhibits recently acquired by the Science Museum through Capt. J. F. Cumming, district commissioner. The ore is smelted in a clay furnace, 5 ft. high, with four clay tubes inserted in the side of the furnace near the bottom for ventilation, and a hole at the bottom of the furnace, which is sealed with clay during the period of smelting, for the extraction of the iron. There is no forced draught. The iron ore is broken into small pieces, about one inch cube, and separated into two kinds, known as the male and female elements. Both, it is believed, must be present before iron can be produced. Sixteen baskets of hardwood charcoal are used to three baskets of ore. One such charge, taking about twenty-two hours for smelting, produces only enough iron to make eight or ten spearheads. The iron collects at the bottom of the furnace and is removed by long poles pointed at the ends, pulled along the ground by native-made rope, and then quenched with water. It is then broken into small pieces for treatment at the forge. The forge is situated in a grass hut, mainly to prevent the sun from shining on the iron. Should this happen, it would be impossible to work it. Great deference is paid to the smith, and oaths sworn on his anvil, a rough piece of iron driven into a palm-tree buried in the ground, are inviolable. The charcoal is raised to the temperature necessary to soften the iron by two rows of bellows, of which the chief interest is that they exactly resemble the bellows used in ancient Egypt and shown on a drawing from a tomb at Thebes of about 1500 B.C. They are made of clay covered with goatskin, and have no valves. The nozzles, therefore, do not enter the fire, but each pair rests in a clay junction unit which has one end in the fire and the other open to the air to admit the inward draught.

Hawaiian Tradition. An interesting document has recently come into the possession of the Bernice P. Bishop Museum, Honolulu, and is edited under the title "Kepelino's Traditions of Hawaii" by Martha Warren Beckwith (Bulletin 95). The manuscript was for some years in the possession of the Roman Catholic Mission of Honolulu, for which it was composed by Kepelino, a descendant of the priestly race of Paao, born in Hawaii about 1830, and transcribed by Bishop Maigret. Although Christian influence is present, the record bears the mark of authenticity and sincerity. Of the gods it is said that three classes of gods were recognised in the history of Hawaii: the great gods, the class of spirits who were created and of men, that is the guardian spirits, and thirdly the class of things without souls. The great gods were male gods; they had no source; they made all things and all power was theirs. These gods made many gods to serve them and they made man and all things. In the second class there were many gods and these were subdivided into three kinds: the spirits without a body, the *aumakua* of day, and secondly the *aumakua* of night, the dead, and in the third class, district chiefs. The last are put in the class of gods because, as ruling chiefs, they had great power and also because of the *tapu* observed towards them, a thing to be dreaded. Also they had the power of life and death. They were called "gods that could be seen". They were sometimes worshipped. The *tapu* of the gods covers all men and all chiefs, while the *tapu* of the chiefs covers only the commoners with the exception of the *kahuna* and his people. The chief's *tapu* had many laws of death, such as that if one did not prostrate oneself when the chief came forth or sit when the chief's bathing water went by, or if one walked about when the chief's name was chanted, the penalty was death.

Indian Microlepidoptera. Scientific Monograph No. 2 of the Imperial Council of Agricultural Research (India) entitled "Life-Histories of Indian Microlepidoptera" has recently come to hand. In this memoir, Mr. T. Bainbrigge Fletcher, Imperial entomologist, has continued his studies of these small moths. The present contribution deals with the life-histories of a number of species belonging to the groups Alucitidæ, Tortricina and Gelechiadæ the transformations of which, in many cases, are figured on the accompanying plates. Notwithstanding their small size, certain of these insects have a very extensive geographical range and included among them are destructive species of great economic importance. Students of the groups concerned will find many hitherto unknown life-histories described. The monograph is issued by the Government Publication Branch, Calcutta (Rs. 3–4 or 5*s*. 6*d*.).

Culture of Snail's Tissue. J. Brontë Gatenby and E. S. Duthie have recorded (*J. Roy. Micr. Soc.*, 52, pt. 4; 1932) observations on the histology of the wall of the pulmonary cavity in *Helix aspersa*. They describe the normal regeneration of the wall after cutting in the living snail, and give a preliminary account of the behaviour of small pieces of the wall when cultivated in hanging drops of the snail's blood. In the process of normal regeneration no mitotic divisions were seen, while figures suggestive of amitosis were extremely common. In no case have the authors seen mitoses in the cultures where cell multiplication is rapidly taking place, but even a few minutes after the tissue has been placed in blood, and put under the microscope, constriction and separation of cells by the amitotic method has been observed. It is concluded therefore that in culture and in normal regeneration, and probably also in normal growth, the cells of the snail multiply by amitosis. The paper is illustrated by thirteen figures. (See also NATURE, 130, 668, Oct. 22, 1932.)

Fluorescence in Ryegrasses. Rapid developments are taking place in the application of Gentner's screened ultra-violet light test for *multiflorum* characters in *Lolium*. The use of the test has passed into routine practice in a number of seed-testing and herbage research stations and new directions in which it is of service are multiplying. In view of the somewhat expensive nature of mercury vapour and other ultra-violet ray lamps, it is satisfactory to find that filtered daylight may be successfully employed. Linehan and Mercer record (*Proc. Internat. Seed Testing Assoc.*, 4, No. 2; 1932) efficient performance of a Dutch instrument for daylight use. A similar instrument of British manufacture is now available. In a recent communication to the Editor, Messrs.

E. W. Hullett and J. W. Calder, of Canterbury Agricultural College, New Zealand, point out that evidently only the longer wave part of the ultra-violet light spectrum is necessary, since ordinary laboratory glass does not markedly reduce the intensity of the fluorescence. These authors report success with several types of ultra-violet ray generator and with daylight passed through a Wood's filter. The fundamental physiological causes of the fluorescence phenomenon remain obscure, and merit biochemical and physical research in view of their probable importance to plant physiology generally. It is interesting to note, however (Linehan and Mercer, NATURE, 131, 202, Feb. 11, 1933), that despite apparent complexity of these causes, fluorescence behaves, in hybridisation, as a simple Mendelian dominant.

Migration of Oil and Natural Gas. Most geologies of petroleum devote considerable space to problems of oil migration within the earth's crust in an attempt to explain how it is that petroleum makes its way into the reservoirs from which it is at the present time produced. Ever since the inception of theories of origin and accumulation of oil, attempts have been made to explain the forces which have caused the movement of the oil through the earth's crust and it must be admitted that there has been a good deal of uninspiring repetition of old theories without regard for the results of experimental work or for the records of field technology now available from well-understood oilfields throughout the world. The study of migration has been made a special one by Prof. V. C. Illing for some years past. His paper before the Institution of Petroleum Technologists on March 7 showed clearly that he is not satisfied with mere repetition of theories. Apart from giving results of experimental work carried on for some years past at the Royal School of Mines, he emphasised that migration is bound to be a twofold process: a primary movement of oil and gas from source rocks to reservoir rocks and a secondary movement of segregation within these rocks and thus the ultimate distribution of oil and gas as pools. Primary migration is ascribed to compaction aided by internal or external sources of pressure, in which phase the oil originates. Secondary migration implies separation of gas, oil and water within the coarse rocks, sometimes due to static buoyancy but probably in the main due to flotation in mobile fluids. Such previously accepted theories as buoyancy, capillarity or hydraulic currents as being responsible, are, the author contends, inadequate, and even Munn's theory fails to explain the retention of oil in coarser rocks.

Photoconductive Effect in Carborundum Crystals. In a communication to the Editor, Prof. Kamienski, of the Institute of Physical Chemistry and Electro-Chemistry, Jagellonian University, Cracow, has observed that some carborundum crystals exhibit a photoconductive effect. A Lindemann electrometer connected across a xylol-alcohol resistance in series with the crystal and a small battery were used to investigate the phenomenon. In a typical case the crystal had an area of 2·5 sq. mm., the xylol-alcohol resistance was of rather less than one tenth the resistance of the crystal in the dark, and a 4-volt battery was used. A small lamp carrying 0·25 amp. at 2·5 volts was used: when it was 1 cm. from the crystal the electrometer indicated 2·2 volts, at 5 cm. it indicated 0·7 volt, and at 10 cm. it indicated 0·4 volt. In contrast with selenium cells, these crystals give very steady and reproducible results. Prof. Kamienski states that the inertia is low; when the crystal is illuminated, the electrometer needle shows immediately a deflection nearly as great as the ultimate equilibrium value, which is attained in 2–4 minutes. Some crystals show a different photo-sensitivity according to the direction the current is flowing; others have an almost equal sensitivity for both directions. Messrs. Adam Hilger Ltd. have carried out experiments on one of these crystals and have confirmed these results. They also found that the range of sensitivity of the crystal was about 3000–5500 A., and that it was most sensitive to light of wave-length about 4000 A.

Photographic Sensitisers for the Infra-Red. In the *Journal of the Chemical Society* for February, Miss N. I. Fisher and Miss F. M. Hamer publish an account of the syntheses of several tricarbocyanines. These dyes are photographic sensitisers for the infra-red between 7000 A. and 10000 A.

New Lens of High Rapidity for Cinematography. Messrs. Carl Zeiss of Jena have placed upon the market a new cinematograph camera lens with an aperture of *F* 0·85. The lens is known as the 'R-Biotar'. It has already proved very successful in providing an X-ray cinematograph record of the pulsating organs of the body. Actually, of course, the fluorescence image produced on a screen was photographed; the great rapidity of the new lens makes this work much more satisfactory than was previously possible. We are informed that the price of the lens in Great Britain is about £48.

Electrostatic Production of High Voltages. Van de Graaf, Compton and Van Atta, working at the Massachusetts Institute of Technology, have developed a very direct method for the production of high direct current potentials (*Phys. Rev.*, Feb. 1). Electric charges are sprayed by point discharge on to the surface of a moving insulating belt which carries them into the interior of a large insulating sphere. The charges are removed from the belt by a point-collector system inside the sphere and the latter becomes charged to a high potential. The charge conveyed by the belt is limited by the electrostatic intensity in the air at the surface of the belt, and the maximum potential is limited by leakage and discharge from the sphere. In a model generator with a pair of 24-inch spheres 25 microamperes was obtained at about 1,500 kilovolts, and this generator was simple and cheap to construct. A very large generator is now being constructed with 15-foot spheres supported on 24-foot towers of shellac insulating compound, inside which the belts are to run. Each of the two spheres will form a laboratory room and a discharge tube will be supported between the two spheres. Simultaneously with the development of the high voltage generator, a discharge tube has been evolved consisting of an insulating fibre (shellac compound) tube with flat metal ends. The electric field around the cylinder is made uniform by providing a spiral indian-ink leak round the outside of the tube. About 300 kv. was applied to a tube of this type without puncture, the voltage being limited by discharge and the current capacity of the electrostatic generator.

Viscosity of Aqueous Solutions. Grinnell Jones and S. K. Talley (*J. Amer. Chem. Soc.*, Feb.) describe some very accurate experiments on the viscosities of aqueous solutions of six salts and also sucrose and urea at 25°. The Ostwald type viscometer was of quartz, internally ground and polished, and the transit of the meniscus was timed automatically by means of a photoelectric cell. The viscosities confirm the prediction made by Jones and Dole on the basis of the Debye theory of interionic attraction that all salts will increase the viscosity of water if measured at sufficiently low concentration. This is the case even for those salts which produce a diminution in viscosity at higher concentrations, including potassium chloride, chlorate and nitrate, ammonium chloride and cæsium nitrate. The viscosity-concentration curves for these salts go through a minimum. Jones and Dole had shown that the fluidity of a salt solution should be related to the concentration by an equation of the form $\varphi = 1 + A\sqrt{c} + Bc$, where A and B are constants. A should be negative for all electrolytes but zero for non-electrolytes, whilst B may be either positive or negative. This equation, based on the Debye-Hückel theory, is found to hold, and the results also confirm the equation of Falkenhagen and Vernon, in which the value of the constant A is calculated in terms of the mobilities of the two ions. In the case of the two non-electrolytes, the square root term was absent, as it should be when no ions are present in the solution.

Oxidation and the Lubricating Properties of Oil. In a paper in the *Proceedings of the Royal Society* for February, R. O. King describes experiments on lubrication by oil in a state of strong oxidation. A blended mineral oil was circulated through a journal bearing, the temperature of the bearing was artificially raised by a gas-burner, and the the oxidation of the oil was promoted by blowing air through the hot oil. It was found that as the trial of a sample of oil proceeded, the viscosity increased slightly, but the bearing friction at high temperatures decreased and the temperature of seizing was pushed up to very high values. In one case, for example, the coefficient of friction had the very low value of 0·00045 with the bearing running at about 250°. The lubrication of a bearing of this kind under ordinary conditions is of the 'fluid friction' type, but the friction observed under the oxidation conditions is too low to be explained in this way, and the author suggests that the 'oxidation lubrication' is of a quite different type in which activated molecules formed in the initial stages of oxidation become attached to the surfaces and build up a boundary layer. The conditions are then something like those of 'boundary lubrication' described by Hardy but the special nature of the activated molecular film permits a surface of very free slip to be formed.

Astronomical Topics

Astronomical Notes for April. Mercury is in elongation as a morning star on April 20, but is not well placed for northern observers. Jupiter and Mars continue to be well placed, in Leo. Mars is stationary on April 13, not far from Regulus; after this it will approach Jupiter until the evening of June 4, when they are only 15′ apart. Neptune is also in Leo. Venus and Uranus are too near the sun for observation; the former becomes an evening star on April 21, but will not be easily observable until June.

An occultation of Regulus is visible in the southern portion of England on the evening of April 6; the northern limit runs roughly from Liverpool to Dover. Many observers are making expeditions to the limiting line, in the hope of locating this with precision. At Greenwich, disappearance occurs at 8.57 p.m., and reappearance at 9.10 p.m., 24° east of the north point. The smallest instrument will suffice for the observation. Other disappearances of faint stars occur in London on April 1 at 10.10 p.m., on April 29 at 10.42 p.m. and on April 30 at 11.30 p.m. Minima of Algol occur on April 1 at 11.40 p.m. and on April 4 at 8.30 p.m.

Comet Pons-Winnecke should be visible with moderate instruments at the end of April and in May. Search ephemerides are given in B.A.A. Handbook for 1933.

Summer time begins on the morning of April 9, a week earlier than usual, owing to the third Sunday being Easter. Summer time is not used in these notes, and should not be used for astronomical records. After April 9, the times given here need to be increased by one hour to give the summer time.

The Minor Planet Amor. This is the interesting planet discovered by M. Delporte at Uccle a year ago, when it approached the earth within ten million miles. It was observed for nearly three months; *Astronomische Nachrichten* No. 5936 contains a careful discussion of its orbit by Dr. A. Kahrstedt of the Berlin Rechen-Institut.

Epoch 1932 April 6.0 Greenwich Time; mean anomaly 0·45458°; arc from node to perihelion 25·24671°, node 171·13239°, inclination 11·93816°, eccentricity 0·4358886, mean daily motion 1329·6154″, semi-major-axis 1·9239201, period 974·718 days. It is pointed out that the period is to that of the earth as 8 to 3, so that 8 years bring about a recurrence of favourable conditions. Search ephemerides are given for the spring months of 1916 and 1924, in the hope that a re-examination of plates exposed then may disclose some images of the planet; these would be of great use in improving the orbit determination, and facilitating the recovery of the planet. Its motion when near the earth is so rapid that the long trails on plates might have been taken for those of meteors.

Since the least distance of this planet is only two thirds of that of Eros, it may be used for determining the solar parallax and the mass of the moon, as soon as its orbit is accurately known.

Measures of Double Stars at the Union Observatory, Johannesburg. Bulletin 241 of the Astronomical Institute of the Netherlands contains further instalments of the systematic survey of the southern heavens for double stars, which is being carried out by W. H. van den Bos with the 26-inch refractor at the Union Observatory. Accurate measures are given for 158 stars; a considerably longer list contains estimates of positions and magnitudes; in about half the stars of the first list the separation is less than 1″, and several are so small as 0·1″. In four cases, closer companions of previously known pairs have been detected. The primaries are nearly all in the Bonn or Cape Durchmusterung, their reference numbers in these being given.

Early Man in East Africa

TO discuss the early human remains recently discovered by the East African Expedition of Dr. L. S. B. Leakey, the Royal Anthropological Institute convened a Conference on March 18 and 19 to examine the material which is now assembled in Cambridge. After hearing Dr. Leakey's exposition of his discoveries, and a general discussion of questions arising therefrom, the conference appointed committees to report respectively on the geological, palæontological, anatomical, and archæological evidence. The reports of these committees were submitted to the conference as follows :—

GEOLOGY

The Geological Committee has considered the problems placed before it from the point of view of the material available for examination and of the stratigraphical evidence. (*a*) Material : i. *Kanjera*. The Committee agreed that the fragments of skull picked up from the surface have the same source as those found *in situ*, their state of mineralisation being similar. ii. *Kanam*. So far as can be determined from the tests made, the mineralisation of the Kanam mandible seems to be the same as that of the rhinoceros bone found in the same deposit. (*b*) Stratigraphical. Of the geologists present on the Committee, two have seen the Kanjera deposits, although not with Dr. Leakey. Others have had experience of similar strata in East Africa, and the rest have brought to bear on the question their general experience of stratigraphical problems. From the evidence supplied by Dr. Leakey, the Committee can see no escape from the conclusion that the Kanjera skull fragments occur in the calcareous deposit which yielded the following fauna : *E. antiquus recki*, etc., as in the palæontological report below, and the implements of evolved Chellean type. Further, that the Kanam mandible was derived from the horizon which yielded implements of pebble-tool type only. This horizon also furnished the following fauna : two species of mastodon, two of primitive elephant, a species of deinotherium and a small variety of hippopotamus.

The Committee, after considering the character of the Kanjera deposit, does not believe that the fragments can have been introduced into the calcareous deposit at a later date, and feels clear that the two fragments said to be found *in situ* belong in fact to the original deposit. Also, those members of the Committee who have seen the deposits in question, support Dr. Leakey in his view that the Kanam and Kanjera deposits antedate a period of great local tilting and faulting and of volcanic activity.

PALÆONTOLOGY

The Committee on Palæontology reports that Kanam East and Kanam West exhibit differences only in the relative numbers of the fossils of different groups. With the human jaw at Kanam West were found close relatives of the two types of rhinoceros still living in the region, a small hippopotamus, a pig, an antelope, fragments of mastodon, two teeth of a very large deinotherium and remains of *Trionyx*. In Kanam East the collection consists chiefly of mastodon with a primitive elephant, deinotherium, and a few specimens of hippopotamus, rhinoceros, horse, and a young monkey.

The fossils from Kanjera have a later aspect. One elephant has dental plates as deep as those of *E. antiquus*, and all the remains of elephant are of Asiatic or European type. At least two antelopes, *Hylœochœrus*, *Phacochœrus*, and a large pig distinct from that of Kanam West, have a very modern appearance. A baboon is remarkable for its comparatively short face. One equine upper molar approaches *Hipparion*, if it does not actually belong to that genus. Typical *Equus* also occurs. Fragments of mastodon, rhinoceros, a giraffoid, hippopotamus, and a carnivore have also been found.

The Committee thinks that the Kanam deposit should be referred to the Lower Pleistocene, in which the deinotherium and mastodon are survivals from the Upper Pliocene. It also thinks that the Kanjera fauna cannot be later than the Middle Pleistocene.

ANATOMY

The Anatomical Committee reports as follows :—

A. Kanjera No. 3.—(1) These specimens exhibit a condition consistent with great antiquity, and the Committee agrees to the correctness of associating all the fragments in question. (2) In the specimens submitted to them the Committee has observed no characteristics inconsistent with the reference to the type of *Homo sapiens*. (3) The absence of a frontal torus seems to exclude Kanjera No. 3 from association with Neanderthal types. (4) Pending further inquiry, the Committee is not able to cite examples of cranial vaults of the thickness characterising Kanjera No. 3 in non-pathological examples of the modern types of *Homo sapiens :* but it notes the occurrence in Piltdown (*Eoanthropus*) and the Boskop calvaria. (5) The Committee has noted the presence of a transverse occipital suture, which is rare in modern crania. (6) While reconstructions must be to some extent conjectural, yet those submitted agree in indicating a cranial length of 200–209 mm. (7) The Committee has observed no detail in the fragment of femur inconsistent with its inclusion in the type of *Homo sapiens*.

B. Kanjera No. 1.—(1) This specimen has been reconstructed by Dr. Leakey and Mr. McInnes from numerous fragments. The Committee accepts their association but is not able to exclude the possibility of some distortion of the actual specimen being manifested in the reconstruction. (2) The Committee sees no reason to distinguish between Kanjera No. 1 and No. 3, either in regard to the degree of mineralisation, or in regard to antiquity. (3) The Committee notes that Dr. Leakey's reconstruction and his placing of the two main pieces of the specimen provide a maximum length of 200 mm., and that the mid-sagittal contour is strongly suggestive of that which has been accepted by it as reasonably representative of Kanjera No. 3. (4) The Committee remarks that Kanjera No. 1 does not possess the great thickness seen in Kanjera No. 3, also that the transverse diameters seem to be less in No. 1 than in No. 3. (5) On the whole survey, the Committee is prepared to associate Kanjera No. 1 and No. 3 as possibly female (No. 1) and male (No. 3) representatives of the Kanjera type.

C. Kanam.—(1) The Committee, having examined the fragment of mandible, agrees that the appearance of this specimen is not inconsistent with the high antiquity assigned to it. (2) With the possible exceptions of the thickness of the symphysis, the conformation of the anterior internal surface, and what seems to be a large pulp-cavity of the first right molar tooth, the Committee is not able to point to any detail of the specimen that is incompatible with its inclusion in the type of the *Homo sapiens*. (3) In arriving at this conclusion the Committee has had regard to the conformation of the parts about the chin. It has noted that the incisor teeth show signs of crowding but has detected no indication of unusual size in the canine teeth.

ARCHÆOLOGY

The Archæological Committee, after examining the material exhibited, submitted the following conclusions :—

At Oldoway, in a continuous stratified deposit, which should henceforth rank as a standard section, a worked pebble industry in Bed I is supplemented in the lower part of II by an early Chellean industry with *coup de poing* and rostroid forms : and the pebble types persist for a while. There are indications of continuity and of a gradually evolving technique between the pebble industry and the Chellean technique. In Bed III the 'later' or 'evolved' Chellean passes on into highly evolved Acheulean industry, which becomes fully evolved in Bed IV. Though scraper types, round butt hand-axes, and flake implements occur, they are not dominant at any point in the series.

At Kanam and Kanjera, stratified deposits include a similar series of industries, and therein the Kanam jaw is associated with the pebble industry, and the Kanjera skull fragments with Chellean implements corresponding with those of the upper part of Oldoway II.

The pebble industry of Oldoway I has no precise counterpart in western Europe, but is certainly anterior to the Early Chellean of Bed II. The Early Chellean culture of Bed II at Oldoway corresponds typologically with the industries of Early Pleistocene deposits in western Europe ; and the uppermost industries of Oldoway IV with those of the Thames valley gravels with Acheulean implements. The types from Zambezi gravels and other deposits in South Africa indicate comparable lapse of time.

There is no reason to doubt that the series from East Africa is of at least equal antiquity with the European, and it may even begin somewhat earlier.

The Conference, after detailed discussion of these reports, and of supplementary information furnished by Dr. Leakey and Mr. McInnes as to the circumstances of their discoveries, accepted the reports ; congratulated Dr. Leakey on the exceptional significance of his discoveries ; and expressed the hope that he may be enabled to undertake further researches, seeing that there is no field of archæological inquiry which offers greater prospects for the future. It especially urged the early organisation of another expedition.

The following were present and concurred in the above conclusions :—Sir Arthur Smith Woodward (chairman), A. L. Armstrong, H. Balfour, Miss D. M. A. Bate, P. G. H. Boswell, M. C. Burkitt, V. G. Childe, L. C. G. Clarke, W. L. H. Duckworth, H. J. Fleure, C. Forster Cooper, V. E. Fuchs, A. C. Haddon, A. T. Hopwood, O. T. Jones, Sir Albert Kitson, L. S. B. Leakey, D. McInnes, E. H. Minns, J. Reid Moir, J. L. Myres, T. G. Mollison, F. Oswald, K. S. Sandford, R. A. Smith, W. J. Sollas, J. D. Solomon, Miss M. L. Tildesley and D. M. S. Watson.

Utilisation of Coal

MR. H. T. TIZARD, rector of the Imperial College of Science and Technology, presided at a symposium on the utilisation of coal arranged by the British Science Guild and held at the Royal Institution on March 27. The large audience, which was representative of coal, coal-gas and oil interests, scientific and technical societies, trade unions and members of Parliament, was addressed by Capt. Bernard Acworth, Mr. Stephen Lacey, Eng. Rear-Admiral W. Scott-Hill, and Mr. A. C. Hardy, after which there was a discussion.

In his opening paper on the "Economic Significance of Coal", Capt. Acworth made special reference to legislative differentiation unfavourable to the expansion of the coal and coal-gas industries. He asserted that the chief consumers of oil fuel are heavily subsidised out of the public purse. The British taxpayer pays most of the cost of maintaining aircraft, passenger and goods traffic : the taxpayer has likewise had to pay £1,600,000,000 to make our roads fit for motor traffic, and part of this vast sum is an indirect subsidy to the oil companies as it is spent on oil residuals. In addition, certain public authorities have made compulsory the use of electricity for lighting and heating purposes in subsidised houses.

Although the demand for fuel has greatly increased during the past twenty years, the output of coal in Great Britain has decreased by 67,000,000 tons a year since 1913, this decrease indicating the extent by which imported oil has replaced coal. This replacement is represented over the period by an unfavourable trade balance of £960,000,000 ; and one million unemployed involving an annual public burden of £65,000,000. These facts, he urged, should be taken into account by our legislators in considering the relative costs and advantages of coal and oil as a fuel.

Mr. Stephen Lacey, who dealt with the "Development of the Use of Gas", claimed that the part played by the gas industry as an instrument in the efficient utilisation of coal is invariably under-rated. The carbonising process in gas and coke-oven works is the most efficient known means of converting coal into smokeless fuel and other convenient forms of heat. One ton of coal carbonised in a gas works will supply the same amount of useful heat as two tons of raw coal used either for direct heating or converted into electric energy, but at present only ten per cent of the total amount of coal used in Great Britain is carbonised in gas works as compared with twenty-five per cent of raw coal burnt for domestic purposes. This is indicative of the conservatism which has to be overcome, but progress is being made.

The use of gas for industrial undertakings is increasing, more than half the output of some supply companies being thus utilised: and quite recently successful demonstrations have been made in the use of cylinders of compressed gas for mechanical road vehicles, which opens up a new field of enterprise for the gas industry, for gas possesses advantages over petrol, particularly in connexion with engine-starting and completeness of combustion. The present need is for industrialists to overcome their bias in favour of oil and to modernise their plants to enable them to take advantage of the greater heat efficiency and lower cost of carbonised coal and coal-gas.

In his paper on "Coal for Sea Transport", Rear-Admiral Scott-Hill expressed the view that the use of coal for sea transport must be determined by various factors, only one of which is the actual cost per heat unit of coal as compared with oil. The material we import is greater in bulk than that which we export, and therefore a double economy is effected if our ships carry a home-produced fuel as a source of heat or 'bunkers'. This was the factor which led to the supremacy of the British mercantile marine in the nineteenth century, but it was accompanied by standardisation of ship machinery and a reluctance to apply the results of modern science by designers of ship engines. Consequently the first oil-fired ships worked at an advantage over the stoker-fed coal-burning ships, in addition to which the use of oil makes it possible to reduce greatly the number of firemen, it is clean and its 'bunkering' can be carried out more rapidly and without interfering with other work in and about the ship—great advantages for passenger ships and the Navy. For example, at full-speed a first-class battleship would need 600 stokers if raw coal were used against 200 required for an oil-burning ship. Nevertheless, if modern methods of feeding furnaces are adopted by coal-burning ships, if fuller advantage is taken of pulverised coal or mixed fuels, and if the Government encourages the better utilisation of coal, there is still a future for the use of coal in sea transport.

Mr. A. C. Hardy claimed that, if the wish of the back-to-coal enthusiasts were realised, the British mercantile marine would probably be swept out of economic existence by sheer weight of the operating superiority of its rivals. The inference to be drawn from the great increase in oil-burning and motor ships must be that they have advantages for certain purposes over coal-burning ships. Since 1914, the world tonnage of oil ships has grown from 1½ million tons to nearly 20½ million tons: the motor ships from ½ million to 10 million tons. In the past ten years, however, in spite of the fact that the tonnage of oil ships has doubled, that of coal-burning ships has decreased from 45½ million to 40 million tons.

In any event, the ultimate criterion must be the reduction of fuel cost, to which problem both marine coal-steam and marine oil-steam designers are applying themselves with assiduity and success: both of these have also to reckon with the fuel figure of the marine Diesel designers. Coal consumption per horse-power hour has now been reduced to 1 lb. as compared with the best oil-steam figure of about 0·6 lb. and the best Diesel figure of 0·35 lb. Oil now possesses the advantage that oil-filling stations are more numerous than coaling stations, in addition to the advantages over coal of cleanliness in use, quickness of 'bunkering', ease of stowage, small amount used, lower labour costs on board, and the smaller space occupied by oil-using plant. The real question, he suggested, is whether or not Great Britain is justified in creating a handicap against oil in favour of coal. This, he asserted, can only be done at great expense to the taxpayer and to the ultimate disadvantage of our mercantile marine.

In opening the discussion, Dr. E. F. Armstrong suggested that colliery owners on one hand and the Government on the other must be held partly responsible for the replacement of coal by coal-gas, electricity and oil as a heat source: the former by their tardy recognition of the need for modern methods of coal-getting, the cleaning and classification of coal, care in transport, and their acquiescence in wasteful and obsolete methods of distribution of coal for domestic use: the latter by the adoption of the quota system. Another factor in the decline in the use of coal is the attitude of the coal producers towards their natural allies, the gas and electricity supply companies, both of which are charged excessive prices for coal and both of which in turn add to their own costs a disproportionate and unnecessary burden of advertising charges. Finally, he suggested that Capt. Acworth's plea for a back-to-coal movement would be more effective if he supported instead of attacking expenditure on those researches directed towards obtaining oil from coal, including hydrogenation of coal.

Major F. A. Freeth added that if the coal producers had spent only a small fraction of what Imperial Chemical Industries Ltd. had spent on research and organisation they would not be in their present wretched plight.

Mr. H. Pirie, who followed, said that the coal industry has now realised the need for action on the lines suggested by Dr. Armstrong and Major Freeth. The Coal Utilisation Council which he represented was formed for the purpose of promoting the sale of coal, to which end an intensive propaganda campaign is to be launched. An information bureau has been set up from which both producers and consumers can obtain advice and information, including assistance on technical and scientific matters.

Admiral Willmott-Nicholson expressed his sympathy with the views of Capt. Acworth and laid stress on the strategic importance of Great Britain being independent of imports of fuel in the event of war. Among others who contributed to the discussion were Dr. Ormandy, Mr. Hamilton Gibson and Mr. Zulver.

In summing up, Mr. Tizard warned his audience against falling into the error of associating too closely our increasing imports of oil with the decrease in the use of coal and with unemployment among the mining population. The fact that less coal is now used for domestic consumption is obviously not unconnected with increased efficiency in its use, and taking a long view, this is an advantage to the nation. It is a melancholy reflection that whereas ten years ago our economists and politicians attributed our industrial stagnation to the failure of industrialists to apply science to their undertakings, they now attribute our economic depression to the success with which science has been applied in industry. The fact is that our industrial supremacy during the greater part of the nineteenth century was due to the skill and assiduity with which we applied science and invention to then existing conditions. It is useless to bemoan changed conditions: our task is still to apply our best scientific brains to the world as it is to-day.

University and Educational Intelligence

CAMBRIDGE.—Appointments to three University lectureships in mathematics will be made in the Easter term, to take effect from October 1. The initial basic stipend of a University lecturer is £200 a year but the General Board may grant an additional allowance of £150 a year to a lecturer who is not a fellow of a College and may also grant a number of years seniority carrying with it an increased basic stipend. Candidates are requested to send their names with any evidence of qualification to Mr. M. H. A. Newman, secretary to the Faculty Board of Mathematics, St. John's College, Cambridge, on or before May 6.

The subject proposed for the Adams prize for the period 1933-34 is "The Mathematical Representation of Unsteady Flow in Fluids". Recent experimental researches on fluid flow close to a solid surface have revealed new facts of which no mathematical treatment has yet been given. Other aspects of the subject that might be studied include the stability of the flow of viscous fluids, the statistical treatment of turbulence and the conditions behind a body moving in a fluid. Each essay should be accompanied by a full and careful abstract, pointing out the parts which the author considers to be new and indicating the parts which are regarded as of more importance than the rest. The prize is open to the competition of all persons who have at any time been admitted to a degree in the University. The essays must be sent to the Registrary on or before December 31. The value of the prize is about £268; the value may be increased when it seems desirable to the adjudicators, on occasions when the prize is divided.

LONDON.—The following appointments have recently been made: chair of civil engineering (Imperial College—City and Guilds College), Prof. A. J. S. Pippard, since 1928 professor of civil engineering in the University of Bristol; chair of physics (Birkbeck College), Mr. P. M. S. Blackett, since 1930 a University lecturer at the University of Cambridge; readership in physiology (Guy's Hospital Medical School), Mr. W. R. Spurrell, since 1931 demonstrator of physiology in the University of Leeds; Cassel lecturer in commerce (London School of Economics), Dr. Vera Anstey, since 1929 lecturer in commerce at the London School of Economics.

ST. ANDREWS.—The Senatus has resolved to confer the honorary degree of LL.D. at the graduation ceremony on June 30 upon the following: The Right Honourable Mabell-Frances-Elizabeth, Dowager Countess of Airlie, Airlie Castle, Kirriemuir; Mr. W. St. C. Baddeley, Castle Hale, Painswick, Gloucestershire (antiquarian and archæologist); Dr. R. W. Chapman, secretary to the Delegates of the Oxford University Press; The Right Honourable Viscount Chelmsford, formerly Viceroy of India, Warden of All Souls College, Oxford; Prof. Carl Neuberg, director of the Kaiser Wilhelm Institut für Biochemie, Berlin, and editor of the *Biochemische Zeitschrift*; Mr. R. S. Pearson, director of the Forest Products Research Laboratory, Princes Risborough; Mr. Evelyn C. Shaw, secretary to the Royal Commissioners for the Exhibition of 1851, and honorary general secretary of the British School at Rome.

DOCTORATES conferred in the sciences in American universities have increased steadily in number from 330 in 1919–20 to 1241 in 1931–32. The titles of the theses are published annually in the "Reprint and Circular" series of the National Research Council together with tables of comparative statistics for ten years. The tables show that last year the maximum numbers of doctorates conferred in previous years were exceeded or equalled in chemistry (420), zoology (127), physics (113), mathematics (75), bacteriology (46), pathology (43), physiology (46) and anatomy (16). Psychology (104) takes fourth place in the list of subjects, botany (79) fifth and engineering (47) seventh.

HIGHER education in Sweden is known in Great Britain chiefly by its fruits, the character of which argues excellence in the institutions in which it is conducted. A convenient summary account of those institutions has been published by the United States Government Printing Office as Pamphlet No. 32 of 1932 (10 cents). The author, who is the specialist for western Europe in the Foreign School Systems Division of the Federal Office of Education, has attempted to give such particulars as will enable university registrars to estimate the value of academic credentials of Swedish-trained students and has therefore described the various curricula and examination systems in use, both in the secondary schools and in the four universities and some sixteen other (specialist) institutions of university grade. The important reorganisation of the Swedish national scheme of education described some time ago in the Board of Education's Pamphlet No. 81 (H.M. Stationery Office, 1930) is still proceeding. Another useful pamphlet (No. 29; 1932) issued from the Foreign School Systems division of the Office of Education is a summary of official certificates, diplomas and degrees granted in France. This includes a graph exhibiting the successive stages of primary, secondary and university instruction.

How schools have been affected by the prevailing economic depression is told in the December issue of *School Life*, the organ of the United States Office of Education. Thanks to the traditional esteem which education enjoys in the United States, school budgets were scarcely affected during the first year of the depression, but they have now begun to feel the pinch of hard times, especially those of the rural schools in which there was but little provision for expenditure on more than the bare necessities. In school budgets of cities with populations of more than 100,000, the effect of the all-pervading financial stringency is seen chiefly in the reduction in the current year by nearly forty per cent in provision for capital outlay, but in most of the States outside the New England group and California, far more drastic curtailments have taken place in rural school budgets. These have involved such measures as the adoption of a shorter term, elimination of some of the school services and even the closing of schools. In one State, 26 schools were closed for want of funds for their maintenance; in another the closing of schools in 25 counties is expected to throw five thousand teachers out of employment and the average salary paid to elementary teachers was reduced by twelve per cent without counting reductions entailed by shortening the school term; some counties have dismissed one out of every three teachers.

Calendar of Nature Topics

April Showers

In England, April is proverbially showery. It is the spring month *par excellence*, in which the air is still cool but the sun is already fairly strong. The worst storms of winter are past, and moderate breezes prevail, but the land surface is much warmer than the sea, and the air which crosses our coasts is warmed rapidly by contact with the ground. On a typical April day ascending currents are formed, giving rise to detached cumulus clouds from which showers may fall, but the clouds rarely coalesce to form cumulo-nimbus, for the amount of moisture in the air is insufficient for the development of the more severe thunderstorms which occur under similar conditions in summer. Sometimes in April, showers may be seen to fall from a cloud but evaporate before reaching the ground.

Tornadoes in the United States

April 7.—Tornadoes are violent whirls of air of small diameter; in the United States they are most frequent and most destructive over the great lowlands of the central and upper Mississippi and lower Missouri valleys, where they sometimes cause considerable loss of life. They may occur in any month and at almost any hour, but are most frequent in the afternoons of spring and early summer. Most tornadoes form in the current of warm moist air which blows from the south in front of a cyclonic depression advancing across the continent from the west. Above this warm southerly wind there is often a cool wind from the north, giving an unstable distribution of the air layers. When, in addition, the ground is heated by sunshine, conditions become very favourable for the occurrence of violent readjustments, which are generally associated with severe thunderstorms and in extreme cases take the form of tornadoes.

Immigration of Summer Visiting Birds

An occasional early bird arrives in Britain in February; the chiffchaff, ring-ouzel, wheat-ear, swallow, sand-martin, and garganey duck are all credited with dates in the latter part of the month, although mid-March is their usual time of arrival. Generally speaking, the tide of normal immigration begins with first arrivals in the second week of March, led by the ring-ouzel and the wheat-ear, and in all about fourteen species of summer visitors have put in an appearance before the month is over. But April is the great month of first arrivals and in the third week of the month the greatest number of species appears, about twelve out of the month's total of thirty. The advance guards are followed within a few days by the general immigration of the species, but often a month or more may elapse before the general movement is completed. Amongst the laggards in reaching their breeding haunts in Britain are the red-necked phalarope, which nests in a few localities in Scotland, where it arrives in the third week of May from its winter haunts in the seas of south-western Europe; and the marsh-warbler, which seldom reaches its nesting sites in the southern counties of England until the early days of June.

The mass arrival of the summer visitors amongst birds is associated with the increase of temperature, for it is in April that the great spring change takes place, and the winter type of temperature distribution, in which inland temperatures are relatively low compared with coastal temperatures, is replaced by the summer distribution of high inland and low coastal temperatures, which continues until the autumn.

Order of the Coming of Summer Visitors

When Dr. Eagle Clarke summarised the vast mass of data on migration accumulated for the British Association Committee of 1896, he found that the great majority of British summer birds appeared on the west coast of England some days in advance of their arrival in their eastern haunts. These observations have been amply confirmed, and it has been found, as Dr. Clarke also has pointed out, that the same rule applies to Scotland, where the Solway and Clyde areas receive their first spring migrants some days earlier than the areas of Tweed and Forth. The records and maps of spring migrant isophenes (or lines of equal arrival dates) published in recent years in the Phenological Report of the Royal Meteorological Society, make still more striking the order of the arrival of the summer birds. From south to north the progress is remarkably steady each year. Within a week of the first arrivals in Kent, the birds are at the Humber, three days later they have reached the Tweed, and in approximately three more days they appear in the neighbourhood of Aberdeen.

Another fact, often referred to, is the regularity with which the individuals of a species arrive at the same place year after year, a testimony to the stability of the seasonal impulse of migration the more striking when the enormous distances traversed between the points of setting out and of arrival are kept in mind. A recent example may be quoted from a paper by Witmer Stone in the Year Book of the Academy of Natural Sciences of Philadelphia for 1931 (1932). For many years the Delaware Valley Ornithological Club has recorded the time of arrival of birds at various places within ten miles of Philadelphia; two examples of their records will illustrate the point—in eight consecutive years the wood-thrush has arrived on April 28, May 2, April 30, April 28, April 29, May 1, April 26 and May 1; and the black-and-white warbler on April 27, 26, 25, 27, 27, 27, 25 and 27. Both birds are easily recognisable, one by its song the other by its coloration, so that there is little chance of either being overlooked or mistaken for another species.

The 'March Brown' of the Angler

The 'March brown', now appearing in great quantity in a number of rivers, is widely distributed in Britain. Well known to the angler for more than a century by its common name of 'March brown' and by other names since the middle of the seventeenth century, it is extremely probable that the 'March brown' is referred to in a well-known description in the "Boke of St. Albans" (1496). It is curious that such a familiar insect should so long have remained unknown to the entomologist, and only recently have found its rightful place in the list of British Ephemeroptera. Eaton (1883) identified it with *Ecdyurus venosus*, an ephemerid different in habits, appearing from mid-May to October, the subimago of which closely resembles the March brown. Moseley (*Ann. Mag. Nat. Hist.*, Jan., 1932) showed the 'March brown' of the early spring months to be *Rhithrogena haarupi*, Esb.-Peters., an insect first described from Denmark (Esben-Petersen, 1909).

Societies and Academies

London

Royal Society, March 23. G. I. Finch and A. G. Quarrell: The structure of magnesium, zinc and aluminium films. An electron diffraction camera is described in which the specimen is swept by a diffuse beam of electrons, thereby reducing the risk of injury to the specimen. The beam is then focused electromagnetically. Oxide-free surfaces of magnesium, zinc, and aluminium on a platinum substrate, also vapours of these metals in transit between source and receiver, were obtained and examined by electron diffraction. The oxides of magnesium and zinc formed on the corresponding metal surfaces have also been examined. It is concluded from the results that (1) the abnormal crystal structures are caused by pseudomorphic strain effects whereby the substrate influences the positions taken up by the atoms of the metal or metal oxide layers formed thereon; (2) such pseudomorphic effects are no longer evident at the surface of sufficiently thick films; (3) for aluminium the pseudomorphic strain effects are confined to the two dimensions of the basal planes, because no such effect was to be observed in the third dimension; (4) magnesium, zinc and aluminium vapours are monatomic. E. C. Pollard: Experiments on the protons produced in the artificial disintegration of the nitrogen nucleus. Experiments to determine the manner of entry of the α-particle into the nitrogen nucleus have been made; these indicate that entry is in general over the top of the barrier, and the height of this barrier is fixed as between $4·1 \times 10^6$ and $4·4 \times 10^6$ electron volts. Further investigation of the absorption curve of the protons confirms the work of Steudel on this element and gives an indication of a second group, which can be ascribed to resonance entry of an α-particle of $3·5 \times 10^6$ electron volts energy.

Geological Society, Jan. 11. C. S. Hitchen: The Skiddaw granite and its residual products. The Skiddaw granite occurs as three isolated, though neighbouring exposures of limited size in the fell country to the north-east of Keswick in the English Lake District. The most southerly exposure occurs at Sinen Gill. It is of the nature of a small apophysis and consists of a porphyritic oligoclase-biotite-granite corresponding to a sub-acid alkali-lime type. The granite of this exposure appears to represent a deep-seated term in the Skiddaw suite. The central and largest exposure occupies an area of about half a square mile and is situated in the valley of the River Caldew. It consists of an albite-muscovite-biotite-granite of a more normal alkali (soda-potash) type, the porphyritic character being less distinct than that of the Sinen Gill rock. The northern exposure at Grainsgill is approximately one-eighth of a square mile in area and appears to be a large apophysis. It consists partly of normal granite and partly of a quartz-mica rock or greisen. It is concluded that the greisen was not formed by the consolidation of mother-liquor extruded from the crystallising magma by crustal disturbances, as was formerly supposed, but that it represents normal granite which has undergone alteration by paulopost hydrothermal solutions. L. G. Anniss: The Upper Devonian rocks of the Chudleigh area, South Devon. The Devonian rocks occur as a number of small, scattered inliers in a region mainly occupied by Lower Culm Measures. The outcrops of Massive Limestone are described, and the Upper Frasnian and the Famennian have been zoned by the cephalopod and other faunas. The Dunscombe beds represent the Manticoceras stage and the base of the Cheiloceras stage (zones 1α to 2α of Wedekind), the Lævigites Limestone and shales represent the Lævigites stage (zone 5), and the Entomis Shales are equivalent to the Gattendorfia stage (zone 6). The succession is not complete, there being a non-sequence between the base of the Cheiloceras stage and the Lævigites stage. The region has been subjected to three distinct earth-movements.

Paris

Academy of Sciences, Feb. 13 (*C.R.*, **196**, 449–512). J. Costantin: Historical résumé concerning conceptions on the degenerescence of cultivated plants. E. Mathias: Contribution to the study of fulminating material. The evaluation of the constant ratio which exists between the final volume and the initial volume in the progressive decomposition at atmospheric pressure when the final temperature is identical with the initial temperature. W. Slebodzinski: The complexes of geodesics in a variety V_3. Alfred Rosenblatt: The theorems of M. Picard in the theory of non-linear partial differential equations of the elliptic type. Paul Lévy: The absolute convergence of Fourier's series. E. Kogbetliantz: The determination of the step $D(x_0)$ of $f(x)$. E. Crausse and J. Baubiac: A modification of the chronophotographic method and some applications. Results obtained by the cinematographic method described were compared with those given by two other experimental methods, hot wire and stroboscopic, and also with the theoretical curve obtained by Szymanski. R. Bossuet: The photographic sensibility of the lines of the alkaline metals in the oxyacetylene flame. Rods of magnesium pyrophosphate were impregnated with the solutions examined at increasing dilutions. Two forms of spectrograph were employed (Féry, Bourguel) and data are given for the limiting sensibilities with lithium, sodium, potassium, rubidium and cæsium. G. Déjardin and R. Latarjet: The spectral sensibility of photoelectric cathodes coated with a cæsium oxide film. Details of the method of preparing the coating and curves of emission as a function of the wave-length. Mlle. Quintin: Study of the electromotive force of the chain: copper, copper sulphate, mercurous sulphate, mercury, at 25° C. The experimental values, used to determine the normal potential E_0 by Lewis's method, do not give a satisfactory extrapolation. René Audubert: The differentiation of the electronic effects and the photoelectric effects in photovoltaic elements. The study of the photovoltaic effects for several frequencies allows, by suitable choice of electrolytes, of distinguishing in the action of light on the electrodes the photoelectrochemical effect from a secondary internal electronic effect. H. Muraour and G. Aunis: The laws of combustion of mixtures of (gun-cotton) powders. F. Bourion and Mlle. O. Hun: The cryoscopy of paraldehyde, acetone and ether in solutions of magnesium and ammonium sulphates. René Dufour: The initial electrolytic overvoltage in the disengagement of hydrogen on mercury. The study of the electrolytic overvoltage of mercury, placed under conditions of reversible equilibrium, appears to lead to the result that the initial overvoltage is nil. Jean Bouchard: The quantitative study of the inhibiting action of some ions on the fluorescent power of uranine. R. Rambaud: Trans γ-oxycrotonic acid. The trans form has been obtained by the complete saponification of ethyl acetoxycrotonate by warm aqueous potash solution. It is stable and does not give a lactone on dehydration. G. Darzens and Maxence Meyer: A new general method for the synthesis of aldehydes. The halogen compound RX is treated with the sodium derivative of ethoxymalonic ester, the latter being readily prepared by the method of Wislicenus, followed by saponification, distillation in a vacuum giving the ester $RCH(OC_2H_5)(CO_2H)$. From the latter the aldehyde RCHO is readily obtained by the method already described by Darzens and Lévy. Examples of the generality of the proposed method are given. D. Ivanoff and I. Abdouloff: *The velocity of disengagement of hydrocarbons produced by the action of indene on fatty organomagnesium derivatives.* A method of measuring the strength of linkage of alkyl radicals with the magnesyl group. L. Berthois: The study of contact metamorphism with the aid of heavy minerals. The method proposed has some advantages over the usual method of thin sections owing to the larger quantities used. P. Fallot: The Xauen massif (Spanish Rif). L. Joleaud and J. Lombard: Quaternary mammals of Ounianga Kebir (South-eastern Tibesti). Marcel Chopin: The influence of the medium on the baking value of bread. Emile F. Terroine, P. Mezincesco and Mlle. Simone Valla: *Utilisation of sulphur and nitrogen from cystine at the level of endogenous protein metabolism.* The addition of cystine to the diet proves that there is no necessary parallelism, in all circumstances, between the metabolism of nitrogen and that of sulphur. The facts cited lend fresh support to the view according to which the protein needs of the organism should be divided into many fractions to a great extent independent. O. V. Amann and Mlle. Gilberte Mourot: The comparative excretion of neutral sulphur in endogenous and exogenous nitrogen metabolisms and its signification. Mme. Andrée Drilhon: Glucose and shedding the shell of crustaceans. At the time the shell is being changed there is a marked increase in the proportion of glucose in the blood. J. Laigret: The sensibility of certain wild mice to the virus of yellow fever.

GENEVA

Society of Physics and Natural History, Feb. 2. W. Schopfer: *Biometric researches on the spores of Mucor.* The measurements carried out on thirteen pairs of strains of *Phycomyces blackesleanus* genetically related between themselves showed that the dimensional characters of the spores (length, coefficient of variability) are not connected with sex. E. Friedheim: The biological signification of melanogenesis. *The biological signification of melanogenesis* is not only in its final product, melanine, but also in an intermediate product, the 'red body', which is a reversible oxidation-reduction system in the thermodynamical sense and functions as a catalyst in cell respiration. P. Rossier: The influence of the absolute magnitude of a star on the *width of the lines of stellar hydrogen.* The relative widths of the lines are independent of the absolute magnitude, whilst the total width of the three lines $H\gamma$, $H\delta$, and $H + H_\epsilon$ increases with the absolute magnitude. G. Tiercy: Note on the respective phases of ionisation maxima and light maxima in a Cepheid. By the combination of the light curve and the curve of radial velocities (or that of pulsation) the present note tends to justify the view that the phase of maximum ionisation (youngest spectrum) precedes the maximum of light. Wakker: Gold-bearing strata of the region of St.-Yrieix (Haute-Vienne). The author describes the deposits as well as the geology of the region and suggests an explanation of their genesis. He studies in detail the Fagassière deposits, those of Tournerie and Ladignac, which are constituted of mineralised quartz veins traversing a granite-gneiss complex.

ROME

Royal National Academy of the Lincei, Nov. 20. U. Cisotti: Translo-circulatory plane current investing an indefinite rectilinear rod: dynamic actions. A. Bemporad: Proper motions and orbital motions resulting from the Astrographic Catalogue of Catania. E. Almansi: The deformations of elastic plates (1). Giuseppina Biggiogero: Geometric views on tensors. Certain questions of tensorial calculation are considered with the help of hyperspacial geometry. R. Caccioppoli: A principle of inversion for functional correspondences and its applications to equations with partial derivatives (2). B. Finzi: Group velocity for waves associated with phenomena. M. Kourensky: Integration of equations to the partial derivatives of the second order with two functions of two independent variables. (2) Systems containing five derivatives of the second order. U. Barbieri: Astronomical-geodetic station at the trigonometrical apex of the first order of Mount Crea in July 1930. Results are given of determinations of azimuth, longitude, etc. R. Zoja: Distribution of the tensions in a solid with a rectilinear axis and a *rectangular transverse section* (4). A particular case is considered in the light of the solutions previously obtained. C. Antoniani: Investigations in the phytosterol group. (2) The sterols of rice husk. A laevo-rotatory sterol, $C_{27}H_{46}O$, melting at 143°, has been isolated from rice husk. The sterol fractions described by Anderson and Nobenhauer (1926) as phytosterol *B*, *C*, and *D* are not definite compounds, but mixtures of the sterol now described with the corresponding dihydro-derivative. A. Baroni: Protoselenosulphochloride. This compound, $SeSCl_2$, obtained by the action of selenium on sulphur monochloride, is a deep-red liquid, boiling at 60°–62° under 20 mm. pressure. It exerts a very rapid vulcanising action on rubber and with colza oil or with carbon disulphide and castor oil it causes instantaneous coagulation. Its action on piperidine results in the formation of monothiopiperidine and the separation of selenium; hence its formula is probably $Se : S : Cl_2$. Nicoletta Sabatucci: The toxic action and elimination of nicotine. (1) *Toxic action of nicotine and oxynicotine.* For a frog weighing 20 gm., the minimum toxic dose of nicotine capable of producing complete paralysis, followed by recovery after a few hours, is 1·2 mgm., and the minimal lethal dose 3 mgm. The lower toxity of oxynicotine, for which the minimal lethal dose is 15 mgm., shows that the toxic action of nicotine depends, at least partly, on the chemical function blocked by the oxygen. (2) Elimination and cutaneous absorption of nicotine and caffeine. If, after administration of nicotine by subcutaneous injection, a frog is immediately placed in 200 c.c. of water, the minimum lethal dose falls, from 3 mgm. with non-immersion, to 1·5 mgm. If, however, the alkaloid is introduced into 200 c.c. of water, the minimum lethal dose is 3 mgm. Similar results are shown with caffeine. The frog evidently manifests a special affinity for the two alkaloids. M. **Mitolo**: Avitaminosis and intoxication. (2) Experimental scurvy and chemical intoxication by metals and metalloids. Ingestion, by a guinea-pig suffering from avitaminosis-C, of mixtures of salts of metals and metalloids in doses non-toxic to normal animals, enhances and accelerates the effect of the food-deficiency.

Forthcoming Events

Saturday, April 1

Royal Institution, at 3.—Developments in Cinematography: A Display of Films, (3) Films in Relation to Aeronautical Research.

Monday, April 3

Royal Geographical Society, at 8.30.—Rev. W. H. Murray Walton: "Among the Mountains and Head-Hunters of Formosa".

Tuesday, April 4

Royal Agricultural College, Cirencester.—Conference on: "The Breeding of Dairy Cattle".

Thursday, April 6

Chemical Society, at 8.—Commemoration of the Bicentenary of Priestley. Papers by Prof. A. N. Meldrum, Sir Philip Hartog and Sir Harold Hartley.

Saturday, April 8

Gilbert White Fellowship, at 2.30—(Annual General Meeting in the Hall of the Art-Worker's Guild, 6, Queen Square, W.C.1).—At 3, Sir John Russell: "Modern Trends in Agricultural Science".

Institution of Naval Architects, April 5–7. (in the Lecture Hall of the Royal Society of Arts, John Street, Adelphi, W.C.2).—Annual Meeting.

Knowledge and Action

THE disproportion between poverty and unemployment and the abundance made possible by power production is leading men everywhere to question the basis of a political and economic system which permits the existence of such a paradox of maldistribution. It is no longer merely a question whether effective measures could be taken if those in authority possessed sufficient knowledge and understanding of the situation, but whether the present system permits them to take any effective action without the whole system being radically reformed. The non-success which has thus far attended the efforts or pleadings of politicians is not only fast breeding a general distrust of their policies but also a disposition to consider far-reaching changes in the structure of society.

A resolution brought forward a short time ago by Lord Melchett in the House of Lords summarises fairly concisely one such point of view:

> "Since under modern scientific conditions productive capacity is unlimited, and since the existence of indigence and unemployment throughout a large portion of the population demonstrates the fact that the present monetary system is obsolete and a hindrance to the efficient production and distribution of goods, in the opinion of this House the Government should bring forward immediate proposals for the economic reforms necessary to enable the subjects of this realm to enjoy the benefits to which their present productive capacity entitles them."

The significance of this resolution lies not in its premises, which might be challenged on both sides, but in the very fact of such proposals being debated in our Second Chamber. That such a challenge to our monetary system, coupled with a plea for the national planning of industrial development, limitation of profits and evolution of a characteristic national economy modelled neither on Fascist nor Soviet lines could seriously have been made in such place would have seemed incredible but a couple of decades ago.

It is idle to ignore the fact that the ordinary citizen is beginning seriously to consider the question why politics have proved so unsuccessful where science has had such great success, and if politicians persist in asserting that a radical change cannot be produced in our existing structure of society, he will be liable to retort: "So much the worse for that structure." In a recent address to the Manchester Literary and Philosophical

Society, Sir Ernest Simon expressed the opinion that the only way of providing a solution to our present problems is by scientific thought and by the application of reason to politics. Research into economic and political affairs on just such scientific lines as are applied to physics is essential and yet in Great Britain such research is almost non-existent. Sir Ernest also endorsed Prof. W. McDougall's plea that research on the physical sciences should largely be diverted to research on economic and political questions.

Evidence of the truth of these observations can easily be found in current affairs. The Salter Report on road and rail transport for example was rushed to a decision in July last but no definite action has yet been taken, and interests which are adversely affected are still able to maintain a barrage of criticism to the first steps which Sir Arthur Salter and his colleagues indicated as urgently required. This, of course, is a typical example of the effect of unscientific and rigid legislation which allows unforeseen situations to create formidable vested interests before they are tackled.

Similarly, the hiatus between action and knowledge in spite of all the lip service to the doctrine of national planning is well illustrated by the position of the textile industries in Lancashire. Through the activities of the Universities of Manchester and Liverpool, the Cotton Trade Statistical Bureau, the Manchester Chamber of Commerce and the various regional planning committees, Lancashire is probably the most completely surveyed area in Great Britain. Lancashire opinion has not been mobilised, however, and the chaotic condition of the cotton industry robs it of any power to influence national policy. We are still without any organisation filling the gap between the type of financial assistance supplied by the city and that required by industry to modernise its plant and improve its marketing organisation, as the chairman of the Lancashire Industrial Development Council, Mr. T. D. Barlow, has pointed out in a letter to the Prime Minister.

On the further plea for Government control and guidance of new industrial enterprise to avoid economic waste, the developments in the canning industry accentuate the need for national policy and action. The rapid erection of new canneries while the majority of those in existence are working at only half capacity jeopardises all planned development for canning, and this new industry, which had every opportunity of starting with a clean slate and avoiding the mistakes which have handicapped the growth of other such industries, is threatened with similar loss of capital and general discouragement through low prices.

It is unnecessary to multiply examples of the imperative need of decisive Government action allied to adequate knowledge in accordance with some deliberate plea on scientific lines, though even more striking evidence could be advanced from the international sphere—disarmament, the tariff situation, Manchuria. However, it is as well to recall that the present position is not entirely novel and differs more in degree than in character from that pointed out by such an acute observer as Walter Bagehot more than half a century ago. Writing in "Physics and Politics", he notes as one mark of advancing civilisation "a diffused disposition to weigh evidence, a conviction that much may be said on every side of everything which the elder and more fanatic ages of the world wanted". To those who urged that not only did committees and parliaments fail to act with rapid decisiveness but also that no one now so acts, he replied that when we have a definite end in view, which we know we want, and which we think we know how to obtain, we can act well enough.

Bagehot's argument that the check which deliberation and discussion have placed on irrational impulse and hasty action is an untold benefit to humanity is further supported by his reminder that the impatience and excessive activity of man is one reason why science came so late into the world and is so small and scanty still in its influence. In the half-century since he wrote, however, the difficulty of relating action to knowledge has become far more acute. Not only is much more demanded of the statesman, administrator and politician, but more also is asked of the electorate. It has to be recognised that frequently public opinion, as Sir Ernest Simon pointed out, will not permit the Government to take right action. To quote a recent address by Lord Irwin : "the democratic State depends ultimately on the average judgment of its average members and it should be one of the main objects of education not to conduct mass propaganda but to win for the young the gift of right judgment in all things and the power to distinguish in public affairs and policy between the genuine coins and the spurious counterfeits".

The misgivings regarding the future of democracy which have been expressed by General Smuts, Mr. H. G. Wells and others are largely prompted by the experience of the power of democracy revealed in the last ten years and the danger of prejudices and passions being inflamed, amid which only the demagogue and not the statesman can gain a hearing. For the selection of the right kind of representatives in this scientific age an educated electorate is essential—informed, honest, public-spirited voters capable of electing representatives qualified by knowledge as well as by eloquence, and capable of trusting their representatives to deal with the problems and situations confronting them.

The enthronement of reason in politics outlined in Sir Arthur Salter's ideas, as in Lord Melchett's or Capt. Harold Macmillan's suggestions for an industrial parliament, involve nothing less than a revolution in democracy. While, however, there is much ground for misgivings in recent history alike in Great Britain and in the United States, there are also hopeful signs to be found of the coming of a new order.

Inadequate as the distribution of leisure at the present time may be, the extent of leisure in the modern world is growing and assuming an increasing importance in the life of each individual. The opportunities for education and for forming an intelligent opinion upon public affairs are multiplying and are being increasingly used, even if there is ample room for improvement. On the other hand, there is already an increasing disposition to experiment in our social and private lives, a sufficiently pronounced tendency to be described by Dr. C. Delisle Burns as the most important social change of the past fifty years.

This readiness to experiment is already disposing many to face the break from traditional methods or outlooks, if thereby there is any reasonable hope of redressing the balance in the present distribution of leisure and work, productive capacity and consumption. There are welcome signs of a new attitude towards science and an increasing disposition both to try new methods and to insist on the relation of administrative or executive power with full knowledge of the technical or scientific issues. The increasing efficiency of the instruments of social change is a further hopeful factor. What is in doubt is whether the progressive forces can be organised sufficiently rapidly for effective action; before the continued misuse, either in industry or in politics, of the immensely greater destructive forces released by the application of scientific discoveries, involves us in irremediable social or economic disaster. The support of scientific workers is an indispensable factor in safeguarding society, and its effective mobilisation is long overdue.

De Sitter's World

Kosmos: a Course of Six Lectures on the Development of our Insight into the Structure of the Universe, delivered for the Lowell Institute in Boston in November 1931. By Prof. W. de Sitter. Pp. xii + 138 + 12 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1932.) 9*s.* 6*d.* net.

THIS book affords the world an opportunity of knowing Prof. de Sitter for what his many friends have long known him to be, a great lover of science and a great lover of art. De Sitter speaks to the English-speaking peoples in a tongue which is not his own by birth, but which he uses with an unstrained eloquence that brings vivid pleasure. He does so by right of his own distinguished contributions to a great subject; and he conceals his weight of technical learning under an appealing simplicity of diction. In these lectures not only astronomers and astrophysicists but also all inquirers after knowledge are shown plainly what de Sitter thinks about the world and why he thinks it worth while to go on thinking about the world. We have here no attempt to stun the reader by force of huge distances, no attempt to drug him with doses of inconceivable periods of time. The book gives the real reasons why men working at astronomical science have drawn the picture as they present it to-day.

The lectures are in form a historical account of astronomical discovery. They deal with the Ptolemaic and Copernican systems, with the great work of Kepler, Galileo and Newton, with the first ideas of the sidereal system developed by William Herschel, with Kapteyn's masterly statistical synthesis of modern observations of what we must now call the nearer stars, with a picture of the galactic system as a whole as expressed in the work of Shapley, J. S. Plaskett, Oort and others, and lastly with the great problem of the expanding universe of spiral nebulæ.

The solar system is definite enough. But the 'local cluster' and the galactic system are, one a convenient working hypothesis for certain purposes and the other a largely unknown monster. Perhaps all will not accept every detail of the picture as painted by de Sitter. It is not certain that a galactic rotation is the only legitimate interpretation of the observed double wave in the radial velocities and proper motions; the evidence for the local cluster is hard to reconcile with galactic rotation; and the phenomenon of star-streaming has not been adequately fitted in to the scheme. These points are discussed by de Sitter in a stimulating way.

Most readers will reserve their greatest interest for de Sitter's handling of the problem to which he has himself notably contributed—the structure of the world of nebulæ as 'smoothed-out'.

Here we must examine both de Sitter's philosophy of science and his present attitude to the problem. De Sitter says that the ultimate aim of science is to discover as much as is discoverable about the reality behind the phenomena. Surely this is not the aim of science, whatever may be the aim of philosophy. De Sitter defends his view by urging that "the laws of nature, after all that is relative, due to the observer, has been eliminated, *are* for us the reality". Again, later, he says, "the development of science is in the direction to make it less subjective, to separate the observed facts from that which belongs to the reality behind the phenomena, the absolute, from the subjective element which is introduced by the observer, the relative. Einstein's theory is a great step in that direction. We can say that the theory of relativity is intended to remove entirely the relative and exhibit the pure absolute".

The reviewer would ask whether the aim of eliminating the observer is in the last resort a legitimate one. In atomic phenomena, the measurements of times and energies, of positions and velocities, have been shown to be related by Heisenberg's uncertainty principle, so that there the act of observation itself cannot be eliminated. In macroscopic phenomena, the observer is eliminated by the construction of 'space-time'. Einstein's special theory of relativity did not abolish the observer: it correlated the observations of two observers in uniform motion. Minkowski showed how these different observations could be welded together into a set of world-lines in space-time. But this does not justify us in assuming space-time to be the real stuff of which the world is made, for that there exists a reality independent of the observer is a pure postulate. Science is concerned with the class or aggregate of all observers' observed worlds, and not with some hypothetical temporo-spatial structure behind them. For each separate observer, the complete time-sequence of his world-views is for him the reality.

The hypothesis that 'space-time' is an element of the real nature of the physical world is deep-rooted in most treatments of the cosmological problem. De Sitter says, "We have no intuitive knowledge of the kind of space we live in. As we are concerned with *physical* space. . . ." Thus he assumes that there is a real existent, 'space', a constituent of the world, capable of being explored. What the properties of the existent space may be has recently been the subject of detailed inquiry by O. Heckmann, de Sitter and Einstein. It has been shown that solutions of the gravitational field equations for the world may be obtained for space of positive, zero or negative curvature, and that various laws of gravitation, with and without the famous λ-term, may be employed. De Sitter has shown (and he emphasises in "Kosmos") that we shall never be able to say anything about the curvature of space without introducing certain hypotheses. This seems to make it doubtful whether the phrase 'physical space' has any objective content at all. If its curvature can never be ascertained, if its curvature is essentially unobservable, then 'physical space' is essentially an arbitrary thing chosen for convenience in describing the world and capable of being chosen in different ways. We are fully entitled, for example, to choose ordinary Euclidean space. This was the point of view of Poincaré. We must, of course, recognise that different ways of choosing space will lead to different forms of expression of the same physical laws. This is illustrated by the inter-relationship shown by Heckmann and de Sitter to exist between the assumed sign of the curvature of space, the assumed sign of the λ-term and the observable quantities, namely the mean density of space and the rate of recession of the nebulæ.

De Sitter concludes that the theory of the expanding universe is at the present moment much less definite than it used to be. "We do not even know whether the curvature is positive, zero or negative, whether the universe is finite or infinite." It would appear preferable to say that questions as to the curvature have no objective content, for the answer is within the analyser's choice, but that questions as to the finiteness of mass or finiteness of volume of the universe have an objective content and are capable of answer either by extended observation or by the application of general principles. De Sitter reminds his readers that the conclusions derived about the expanding universe depend on an assumed homogeneity and isotropy, and that it is not inconceivable that this hypothesis may have to be given up, or modified, or differently interpreted. The uncertainties in the present views on the structure of the universe seem thus to arise out of the assumption of an underlying reality, space-time, and the assumption of homogeneity. De Sitter's last judgment is that our conception of the present state of the universe bears all the marks of a transitory structure. His account of the problem may be commended as a highly objective and dispassionate scientific study, free from all mysticism, possibly the best account available.

Further Light on the Schneider Mediumship

National Laboratory of Psychical Research. Bulletin 4: An Account of some Further Experiments with Rudi Schneider; a Minute-by-Minute Record of 27 Séances. By Harry Price. Pp. 199+23 plates. (London: National Laboratory of Psychical Research, 1933.) 10*s*. net.

THIS book is a vivid account of a series of sittings held in 1932 under the auspices of the National Laboratory of Psychical Research, an organisation directed by Mr. Harry Price and supported by a number of people interested in the subject, such as Dr. Hans Driesch, Prof. William McDougall, Prof. J. C. Flügel, Dr. R. J. Tillyard and Dr. Eugène Osty. The medium under investigation was Mr. Rudi Schneider, who has already been the subject of several books, of which one, concerning recent developments, was reviewed in these columns on June 25, 1932. It is as a supplement to that work that the present volume is especially interesting.

The problem of the Schneider brothers and of their mediumship has for long excited the most embittered controversy. Suspicions have been freely ventilated, but it was not until about 1925 that light began to be apparent. It was suggested that in order to describe the phenomena in normal terms the use of a confederate must be assumed. In order to test this hypothesis Mr. Warren J. Vinton, an American observer and a former colleague of Dr. E. J. Dingwall in the latter's private inquiry into the phenomena of Mr. Willi Schneider, visited the Schneider family in Austria, and in his report describes the methods used by the brothers in their séances. He states that he came into contact with what seemed to be a figure crouching behind the medium's chair; and, in a brief but brilliant analysis, shows how the phenomena could be roughly divided into two main classes—those produced with the aid of a confederate and those produced by the surreptitious freeing of one hand from the control.

In 1927 the use of the confederate was studied by an official of the American Society for Psychical Research who was previously highly unsympathetic to the theories evolved by Dr. Dingwall and Mr. Vinton, but who later admitted in his report that all the essentials of that theory were verified and all the conditions required for its fulfilment were reproduced.

In 1929 and in 1930 further experiments were conducted by Mr. Price in London. Striking phenomena were recorded and again it seemed clear that, if the manifestations were normally produced, confederacy must be assumed.

In 1931 and 1932 Mr. Rudi Schneider was in Paris under Dr. Eugène Osty, the Director of the Institut Métapsychique and a vice-president of Mr. Price's organisation. A series of remarkable phenomena was recorded. It was alleged that the medium possessed the power of externalising a 'force' or 'substance' which demonstrated its presence by interrupting infra-red rays. The report was received with considerable interest in scientific circles, although the record, as printed, lacked many details wholly necessary to a proper understanding of Dr. Osty's methods. Further light is now shed upon these by Mr. Price, who reveals the fact that Dr. Osty was aware of the presence of a confederate in his own laboratory, whilst omitting this significant fact in the official report of the sittings held at the Institut.

The present work carries the inquiries a step further. It does more than that. It gives as intimate a glimpse of the conditions obtaining at 'scientific' inquiries as Mr. Vinton's report gave of the conditions in the Schneiders' own home. The ear-deafening uproar: the forced gaiety of the observers: the attempts to distract the attention and to stifle every sense: the groaning and panting of the medium and the occasional screams of the sitters—all the features which make up these exasperating inquiries are found faithfully recorded in these graphic records.

On one occasion a photograph was taken in which the left hand of Mr. Rudi Schneider is seen, freed from the control and stretching backwards towards the cabinet curtains. This is the first piece of photographic evidence illustrating this manœuvre, although its constant occurrence has been suspected for many years. In another photograph Mr. Willi Schneider is shown in the early stages of his 'mediumship' in the process of demonstrating an alleged materialisation attached to a curtain by a safety-pin!

As regards the supposed psychic interruption of infra-red rays as recorded by Dr. Osty, Mr. Price states that, although results were obtained with one piece of apparatus, with another much more sensitive instrument supervised by officials from the Radiovisor (Parent) Co., Ltd., no abnormal changes whatever were registered.

Such are the new facts in the history of the Schneider mediumship. The theories of confederacy and the freeing of one hand from the control have both received further support; and nothing of any importance has been added to indicate that Mr. Rudi Schneider possesses any supernormal faculties whatever.

Francis Bacon

Francis Bacon: a Biography. By Mary Sturt. Pp. xvi + 246 + 12 plates. (London: Kegan Paul and Co., Ltd., 1932.) 10*s.* 6*d.* net.

IT is many years since we were last given a life of Francis Bacon and in the interval science has come to play an essential part in the very machinery of the State as in its structure and every-day business. We have reached a stage in the world's development when its continued progress demands that the man of science assume those ruling functions which Bacon portrayed him as exercising in the "New Atlantis". While, therefore, the "Novum Organum", the "Advancement of Learning" and the exquisite fragment the "New Atlantis" have a meaning for us which the Victorian age could scarcely have sensed, the general impression of Bacon is derived largely from his own essays, coloured by Macaulay's brilliant but unbalanced polemic.

In the present volume, Miss Sturt endeavours to restore the balance and set the figure of Francis Bacon in a true perspective against the passions and prejudices, the schemings and struggles for power in the midst of which he moved for fully forty years. The story is indifferently told and the biographical material is second-hand, but we see the essential Bacon as he may have appeared to his contemporaries—cold, always old for his years, ambitious, indefatigably industrious, shrewd and competent; a man whose talents inevitably led him to the highest legal office, yet much more than the mere lawyer, for his interests extended to literature, to philosophy, to the theory of science, to gardening; and whatever he touched he adorned.

The pageantry of Elizabethan and Stuart life against which Miss Sturt sets her subject is apt to distract or confuse the mind, but the book gives a popular version of Spedding's work which, if disdained by the scholar, should be of value to the general reader.

From the point of view of the scientific worker, the space devoted to Bacon as a philosopher of science is all too meagre. A skilful exposition of Bacon's contribution to the philosophy of science should indeed be of value in the present age when every laboratory might be decorated with his texts and every international society turn to him for a motto. Of Bacon as a philosopher Miss Sturt writes with sympathy and insight, but a brief, popular exposition of his views on science as set forth in the "Advancement of Learning", in the "Novum Organum" and in the "New Atlantis", so sadly neglected by most scientific workers, is long overdue. Even the brief outline contained in the present work, however, should serve as a timely reminder of Bacon's place as one of the true prophets of modern science and induce scientific workers to consider anew his attempt to formulate a technique of discovery, and his vision of a State where the man of science is ruler and where knowledge is harnessed to man's needs.

This vision, born of Bacon's closing years of adversity—he died on April 6, 1626—has the human qualities so often disregarded in ideal commonwealths, and reveals Bacon as one who first in the modern world looked full at facts. To him there was no sphere of life to which scientific thought did not penetrate and he saw too that the scientific method did not rob life of its human values. This vision and the balance of his mind suggest indeed that it is perhaps to a combination of the legal mind trained to assess values, and the scientific mind with its capacity to explore the facts, that we must look for the quality of mind demanded of leaders in the modern State, of whom Francis Bacon himself is both forerunner and type.

Short Reviews

Before and After Socrates. By Prof. F. M. Cornford. Pp. x+113. (Cambridge: At the University Press, 1932.) 4*s.* 6*d.* net.

The elementary character of these lectures scarcely veils the scholarly and human vision of Greek philosophy, hinted at by Prof. Cornford. Taking Socrates as the central figure of Greek philosophy, he describes how the early Ionian science failed to satisfy him, and how the systems of Plato and Aristotle attempt to carry into the interpretations of the world the consequences of Socrates' discovery. The reading of Prof. Cornford's book adds to one's conviction that the fundamental problems of knowledge, as treated by the Greeks, bear a strange resemblance to the major preoccupations of to-day's thinkers. T. G.

The Electrical Age: being Further Everyday Marvels of Science. By V. H. L. Searle. Pp. 229+3 plates. (London: Ernest Benn, Ltd., 1932.) 10*s.* 6*d.* net.

The variety of content of this book will appeal to those who are interested in the application of electrical science to everyday life. Mathematical methods are avoided in order to help the general reader, but the author writes with care for detail as he deals with such diverse subjects as a Sprengel pump, the measurement of time, of high and low temperatures, and the manufacture of gramophone records. The volume provides, in a very readable form, scientific descriptions of many electrical devices, with non-technical statement of underlying principles.

Archaic Tracts round Cambridge. By Alfred Watkins. Pp. 61. (London: Simpkin Marshall, Ltd., 1932.) 3*s.* 6*d.*

Mr. Watkins applies his well-known theory of the sighting relation of prehistoric roads and trackways to mounds, earthworks, churches (as marking older sites), cross-roads, etc., to the Cambridge district. This is the result of a flying visit and most of the work has been done 'on the map'. The author has elaborated a further theory that roads were aligned in reference to cardinal points. The theory is also worked out here for some of his surveys in Herefordshire. Mr. Watkins's work is stimulating, though opinion may differ as to its interpretation.

Practical Physics. By William R. Bower in collaboration with Prof. J. Satterly. Third edition (revised and enlarged). Pp. viii+492. (London: University Tutorial Press, Ltd., 1932.) 7*s.* 6*d.*

That a third edition of this well-known book is called for is clear evidence that it meets a real need in a satisfactory manner, and no one concerned with the teaching or supervision of practical physics will need informing as to its quality. Opportunity has been taken thoroughly to revise the book and bring it into line with modern teaching and examination requirements, increasing its value by the inclusion of new experiments and descriptions of current laboratory practice and apparatus.

Das Vorwort zur Drogenkunde des Bērūnī. Eingeleitet, übersetzt und erlautert von Max Meyerhof. (Quellen und Studien zur Geschichte der Naturwissenschaften und der Medizin, Band 3, Heft 3.) Pp. 52+18. (Berlin: Julius Springer, 1932.) 7.80 gold marks.

This is a very welcome critical translation of the famous "Kitab-i-saidana", referred to for the first time by H. Beveridge in 1902, which exists only in the Persian translation of Abu Bakr. It gives a mass of useful information about certain drugs and chemicals used in the early Middle Ages, and contains precious indications about the corresponding Greek renderings of these substances.

Handbuch der anorganischen Chemie. Herausgegeben von Prof. Dr. R. Abegg, Dr. Fr. Auerbach und Prof. Dr. I. Koppel. In 4 Bänden. Band 4, Abteilung 3, Teil 2B, Lief. 2: *Komplexe Cyanide des Eisens.* Pp. Bxvii–Bxx+B465–B674. (Leipzig: S. Hirzel, 1932.) 24 gold marks.

A detailed account of the complex cyanides of iron, with a bibliography which includes 1,360 references. The frontispiece is a reproduction of early references to Prussian blue by an anonymous writer in 1710, by Woodward and by Brown in the *Philosophical Transactions* of 1724 and by Stahl in 1731.

The Philosophy of a Scientific Man. By Paul R. Heyl. Pp. 182. (New York: The Vanguard Press, 1933.) 1.50 dollars.

This book, which makes delightful reading, could not pretend to contain anything new. It is an act of faith of a scientific man, an act of faith in the purposiveness of the universe and in the power of our reason to apprehend the vague outlines of the reality in which we are embedded. In spite of some hasty generalisations and technical inaccuracies, it should be considered as a valuable testimony at a time when it is still fashionable in certain quarters to disclaim any value for the transcendental concepts of philosophy.

Vox Naturae. By Edwyn Terbea. Pp. 191. (London: Arthur H. Stockwell, Ltd., n.d.) 6*s.* net.

Independent thinkers need every encouragement when they realise the difficulties of the problems of knowledge and conduct, and the relative value of their contributions to their clarification. Mr. Terbea's philosophical outlook will thus appeal to many, in so far as he treats most issues with common-sense and conviction, using as explanatory principles the interfusion of primal, sexual and intellectual urges. T. G.

Progressive Lightning: A New Stereoscope

By Dr. C. V. Boys, F.R.S.

A MOST interesting and illuminating paper on the subject of progressive lightning by Dr. E. C. Halliday[1] describes the results of successful experiments made by himself in South Africa at the instance of Dr. B. F. J. Schonland with an instrument similar to that which I made in the year 1900. As I gave the first description of my instrument in NATURE[2] and have contributed other articles on this subject exclusively to these columns[3] I should be glad to use the same medium for some observations on Dr. Halliday's paper and at the same time describe a new stereoscope designed to examine these photographs without cutting them and also to obtain the physiological advantage of contrast due to reversed stereoscopic effect.

The method of examination of the progress of a lightning flash depends on the use of two images of the flash carried over a photographic plate at a high speed in opposite directions, or of a photographic plate or film carried past two images of the flash in opposite directions. If, then, any part of the flash is subsequent to any other part to an extent visible on the images, these will be distorted in opposite directions and a comparison of the images will give all the information available.

I had the temerity to invent this method of attack in the year 1900 and within a week I had constructed myself an instrument for the purpose. I carried this instrument about, chasing lightning without success, until in the year 1928 I caught up with a flash in America. This photograph, reproduced in NATURE of September 1, 1928, clearly demonstrated that my idea that lightning might occupy some appreciable time while blazing its trail was correct, and Dr. Halliday's photographs confirm this as well as my prediction that an immediately subsequent flash along the same path would be so quick that no aberration would be apparent in the images.

Dr. Halliday's instrument is somewhat less powerful than mine of 1900 but it appears to be ample for the purpose of getting measurable aberration. These instruments are far less powerful than that which Mr. Loomis has at Tuxedo Park, New York, or than the one of similar design which Prof. Adolf Matthias informed me in 1929 that he was going to make. I have not heard whether this instrument ever was made or, if so, whether he has obtained any results. Mr. Loomis and Prof. R. W. Wood have been hunting lightning for two summers with the instrument illustrated diagrammatically in NATURE of July 13, 1929, but so far without success. This perhaps is not surprising, since it was twenty-eight years before I caught a single flash. Thanks to the courtesy of Mr. Goodlet of the Metropolitan-Vickers Electrical Co., Ltd., I was able to test this instrument on their high tension sparks before sending it out to Mr. Loomis. There was never any question of observing progressive development of the 5-ft. spark, but the photographs were so perfect, more especially when Tesla sparks were examined, that the good behaviour of the instrument was assured beforehand. This instrument was constructed by Messrs. Ross, Ltd., at their Clapham works and it is as perfect as such a thing can be. My only fear was that perhaps lightning might be too slow for corresponding pairs of images to be recognisable as being of the same flash.

My method of investigating the progress of a lightning flash has also attracted attention in Western Australia and in Western America, but not apparently in England. I need scarcely say that it has been a source of great satisfaction to me to see Dr. Halliday's paper on his work in South Africa. He sent me an advance draft last autumn but I felt unable to make any reference to it until it had appeared. For this reason I have held back for six months the description herewith of a new stereoscope for observing the progressive character of a flash. That is, unlike any other stereoscope, the instrument indicates time or delay and not solid form.

Coming now to Dr. Halliday's photographs, my object just now is to consider not exactly how his flashes behaved, where they started or how long they took to cover their course, but in the first place to refer to a new point which he has made. It is a little curious that in my American flash, the two images happened to be one above the other and so to be moving horizontally at the time of the flash. Any aberration would result in a bending or a tilting in opposite directions of the two images of the flash, which was nearly vertical. In Dr. Halliday's photographs, on the other hand, the two images happened to be at about the same level and so were moving vertically. According to the aberration that I had contemplated, this would lead to a lengthening of one image and a shortening of the other, and in that case the stereoscope would indicate exactly the same time relief as with the lenses in the other position. Dr. Halliday, however, introduces a new idea. He imagines a flash starting at the cloud and moving downwards. Then he says that the starting point of the flash will remain luminous all the time that is occupied by the flash in travelling to its other end. I suppose he means that electric current would be pouring in at the starting point all this time and keeping it alight. In such case, with the images moving vertically, one image moving towards the cloud's image would, he says, be of its proper length, for the image of the upper end of the flash would be carried towards the cloud exactly to the same extent that the image of the lower end would be carried towards that of the upper end. On the other hand, the other image would be shortened exactly as I have always contemplated. Unfortunately, Dr. Halliday had such wide angle lenses, *F* 2·7, that he had far too much light and his photographs are much spoilt by glare. In my original camera, I used about *F* 8 and with about one-eleventh of the light obtained clear images. I expect *F* 11 or even *F* 16 would give sufficient illumination for the main flash.

Now if my conclusion that the American flash began in the middle is correct, it is difficult to see where the reservoir was to keep up the current. Also, as a matter of fact, the images do not show any broadening at the centre or anywhere. Had current been poured in all the time that the flash was travelling, the image where it started would have been wider than where it finished. According to my view, this lightning flash had some similarity with the flames over a coal fire. Anyone looking at these would believe that the flames were continuous, but if he will look through a moving slit so as to catch a rapid succession of momentary views, he will see that the flame is broken up into a number of elements, and it is the travelling of these upwards in succession that gives the appearance of one long continuous flame. A cinematograph view would be of interest. Similarly, my photograph with images of the same width throughout but slightly different in shape indicates to me that the bright part of the flash travelled from the starting point to the terminal points and that the starting point was not luminous all the time that the flash lasted.

It may well be that no two flashes behave alike and I am not making any point of this difference of view. The real interest to me as an experimentalist is the evidence that the method is capable of ascertaining the facts whatever these facts may be, rather than in worrying over any initial differences in outlook. It seems to me to be far more important to find out what lightning really does than to trouble about ideas of what it ought to do.

It might be worth while to use four lenses equally spaced round a circle so as to obtain for every flash confirmatory evidence of its progress.

The New Stereoscope

Fig. 1 in Nature of September 1, 1928, was obtained by cutting a print in two and rotating each half through a right angle. To ensure this, a straight line had been ruled on the original negative close to and parallel to the line joining the two images, and the two half prints were turned through a right angle until these became vertical. I have found that if I cut up two prints and put two images on each side close together but reversed, that is each the same way up but so that one pair have their sharp edges adjacent while the other have their fading away edges adjacent, the stereoscopic effect of the two pairs is reversed and the contrast makes the effect the more conspicuous.

It is desirable, however, to be able to examine stereoscopically a print without cutting it, and if the contrast due to reversal can be obtained so much the better. This can be done in the following way. Make up a stereoscope by cutting a double convex lens in half and mounting these with their cut diameters away from one another. Then make two isosceles right angle prisms of glass truncated so that the right angle is absent and only the useful part near the hypotheneuse remains. The result is a rectangular prism with inclined ends and the rectangle is best a square. Fig. 1 shows how I have slit an ordinary reflecting prism into three pieces, utilising the two bottom parts. Mount these in two tubes so that they act as reversing mirrors when anything is seen through them. Mount these tubes above the two half lenses at eye distance and arrange that each tube can be turned on its own axis through a right angle, limited at each extremity by screw stops. If now the prisms in these tubes are so placed and moved that all their corresponding edges are always parallel except for the slight convergence, and the square prisms are placed corner-wise so as to turn the images round in the same direction through a right angle as seen by the eyes, these images will then show stereoscopic relief if they are different in form due to aberration. If, then, the tubes are suddenly turned each through a right angle, the images will both be inverted in position and the stereoscopic appearance will be reversed, thus by contrast accentuating the stereoscopic effect. Fig. 2 shows the optical parts only in one position.

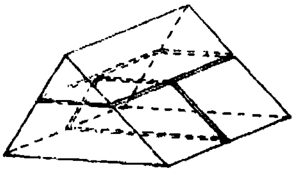

Fig. 1

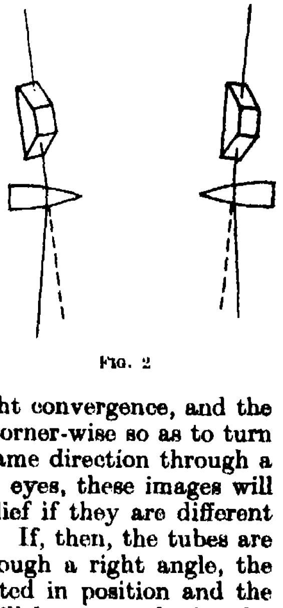

Fig. 2

It may be worth while to say that the shorter the image of a flash is the greater is the stereoscopic impression, because the apparently further and nearer parts, that is, actually the earlier and later, are more closely adjacent on the plate. For this reason it is well to photograph lightning which is not nearer than four or five miles. Short focus lenses also have an advantage in this respect over lenses of longer focus. I did succeed in obtaining with my original instrument quite a spectacular photograph of lightning not a quarter of a mile away and two others on the same plate within a mile. Unfortunately, they are all so much to one side that part of one image of each is off the plate. These were obtained in the night of August 29, 1930, when a terrific thunderstorm of blinding flashes came to St. Marybourne from Winchester, but no flashes were clear of obstruction by rain until they were close up.

Dr. Halliday has made no reference to the stereoscopic method of examination. In his photographs the process of measurement with a micrometer microscope is easy as the aberration is longitudinal. In my photograph where this is transverse, I found measurement with Mr. Loomis's fine micrometer microscope too tedious and the stereoscopic method much more convenient.

I should like in conclusion again to appeal to lightning observers suitably placed to initiate a lightning flash with a rocket. I gave some indication of what to do in my article in NATURE of November 20, 1926, but if anyone should care to consider this more closely, I would recommend the construction of a 'towering rocket' of suitable proportions which should have great persuasive power. Long ago I made a 1 lb. rocket to carry a 6 oz. rocket in its head and this again to carry a 2 oz. rocket which, of course, had the usual stars. The conducting trail which such a combination creates in a very short time and up to an immense height, should initiate a flash almost with certainty if a new flash should be becoming due.

---

Researches on Gaseous Combustion*

By PROF. W. A. BONE, F.R.S.

HYDROCARBON COMBUSTION

IN reviewing, in my recent Bakerian lecture, the principal researches upon the combustion of hydrocarbons, the importance was stressed of a balanced judgment embracing the whole range of conditions from slow combustion through flames and explosions right up to detonation. For it is only by taking all conditions into account comprehensively that a true view of the subject can be gained.

It was shown how the hydroxylation theory is capable of expressing the principal facts of both the slow and explosive combustion of gaseous hydrocarbons. For although the conditions prevailing in flames are obviously much more complex than those of slow combustion, the main course of the chemical changes concerned therein may be satisfactorily interpreted on the supposition that the result of the initial encounters between hydrocarbon and oxygen is the same in both, namely, the formation of an 'oxygenated' which (except with acetylene) is a 'hydroxylated' molecule. Undoubtedly, at the higher temperatures of flames, secondary thermal decompositions occur and play a more conspicuous rôle than in slow combustion; but there are the strongest experimental grounds for believing that they do not precede the onslaught of the oxygen upon the hydrocarbon, but arise in consequence thereof. In particular, all the evidence is quite decisive against such views as that of a 'preferential' combustion, whether of hydrogen or carbon, or that in an explosion flame the hydrocarbon molecule is primarily resolved into its elements before being burnt.

Experiments were made showing that the affinities of hydrocarbons so greatly exceed those of either hydrogen or carbonic oxide for oxygen that in explosions of hydrocarbon–hydrogen (or carbonic oxide)–oxygen media deficient in oxygen the hydrocarbon is burnt, as it were, preferentially. Perhaps the most striking experiment of all consisted in exploding a mixture of 25 per cent of acetylene and 75 per cent of electrolytic gas in a stout glass bulb at a pressure of (say) 500 mm. (higher could be used but for the danger of shattering the vessel). A sharp bluish flame filled the vessel, but neither carbon separated nor did any steam condense on cooling, the products consisting of carbonic oxide and hydrogen with traces only of carbonic anhydride or of methane, in accordance with the equation:

$$C_2H_2 + O_2 + 2H_2 = 2CO + 3H_2.$$

A similar result was also obtained on exploding a mixture of equal volumes of ethylene, hydrogen and oxygen, thus:—

$$C_2H_4 + O_2 + H_2 = 2CO + 3H_2.$$

Another most arresting and significant feature of the evidence, also illustrated experimentally, was that whereas all the hydrocarbons of the C_nH_{2n} series, that is, ethylene, propylene, trimethylene and butylene, on explosion with a $C_nH_{2n} + \frac{n}{2}O_2$ proportion of oxygen always yield substantially carbonic oxide and hydrogen only, as though there had been a preferential burning of their carbon, thus:

$$C_nH_{2n} + \tfrac{n}{2}O_2 = nCO + nH_2,$$

explosions of corresponding members of the C_nH_{2n+2} or paraffin series (that is, ethane, propane or butane) with oxygen in the $C_nH_{2n+2} + \frac{n}{2}O_2$ proportion, all result in dense clouds of carbon, steam, methane and oxides of carbon. This striking difference between the behaviours of corresponding paraffins and olefines accords well with the hydroxylation theory.

Moreover, in regard to olefine explosions, another significant fact is that, so soon as the proportion of oxygen in the medium is progressively reduced below the $C_nH_{2n} + \frac{n}{2}O_2$ proportion, steam (as well as carbon) begins to appear in the products and relatively increases in amount as the oxygen content diminishes. This was demonstrated by exploding a $3C_2H_4 + 2O_2$ mixture and it points unmistakably to the initial formation of 'hydroxylated' molecules in such explosions.

In recent years, however, the suggestion has been made that the initial association of hydrocarbon and oxygen molecules in explosions results in a 'peroxidation' rather than a 'hydroxylation', but on closer examination the evidence of such 'peroxidation' has broken down completely. In the first place, whereas in no case of slow combustion of the gaseous hydrocarbons referred to has the postulated initial 'peroxidation' been proved by the isolation of the particular peroxide involved, abundant evidence of the initial formation of alcohols has been forthcoming from experiments on the pressure-oxidation of methane and ethane. Secondly, in the latter case, recent experiments by Dr. D. M. Newitt and Mr. A. M. Bloch in our laboratories have afforded quantitative proof of the hydroxylation theory, no peroxides whatever being found at any stage of the process. Thirdly, in such slow oxidation, the shortest 'induction' and 'reaction' periods are obtained with 2-hydrocarbon-1-oxygen instead of with equimolecular mixtures. Fourthly, experiments upon the induction period have definitely proved that the formation of an aldehyde always *precedes* that of any peroxide, the latter being rarely (if ever) observed. Finally, the 'peroxidation' theory is countered by the results of exploding under pressure methane-oxygen mixtures of compositions intermediate between $5CH_4 + 2O_2$ and $CH_4 + O_2$. Indeed, all the evidence points to any slight peroxide formation which may sometimes be observed during hydrocarbon combustion being a relatively late and minor side occurrence dependent upon a prior formation of aldehyde.

---

* Substance of the Bakerian Lecture (*Proc. Roy. Soc.*, A, 137, 243–274) and papers read afterwards at the Royal Society on Nov. 10, 1932 (*ibid.*, A, 137, 57–88).

EXPLOSIONS AT HIGH PRESSURES

In continuance of researches upon gaseous explosions at high initial pressures carried out for many years past by Drs. D. M. Newitt, D. T. A. Townend and myself at the Imperial College, we have recently published further results of experiments upon (1) hydrogen–air and carbonic oxide–air explosions at initial pressures between 250 and 1,000 atmospheres, and (2) the formation of nitric oxide in carbonic oxide–oxygen–nitrogen flames and explosions.

The previous work had resulted (*inter alia*) in the discovery of a nitrogen activation in $CO–O_2–N_2$ explosions at high initial pressures, due to an absorption by nitrogen molecules of the radiation emitted by the burning carbonic oxide, the effect steadily increasing with the density of the medium but apparently approaching a maximum at initial pressures of about 150 atmospheres, although its intensity relative to the total kinetic energy developed had been greatest at $P_1 = 75–100$ atmospheres. The new experiments were designed to show not only (*a*) how much further the effect would increase with the density of the medium, but also, (*b*) in presence of excess of oxygen, how much of the nitrogen thus activated would form nitric oxide during the explosions, the latter consideration being of importance from the point of view of a possible commercial process for the direct fixation of nitrogen.

In investigating (*a*), a special super-pressure bomb, with a cylindrical explosion chamber 3 in. long and 1½ in. in diameter (capacity 115 c.c.), capable of withstanding explosion pressures up to 10,000 atmospheres (with a safety factor of 4), was employed; and the pressures actually developed far exceeded any yet recorded in any explosion experiments. For determining (*b*), a $2CO + 3O_2 + 2N_2$ mixture, which is the most favourable of all to the formation of nitric oxide, was exploded at various initial pressures between 40 and 88 atmospheres in a nickel-steel bomb (explosion chamber = 990 c.c.) in such-wise that at some predetermined moment during the explosion a steel disc partition was burst suddenly, liberating the gaseous products into a large 'expansion chamber' (capacity = 38 litres) from which they were afterwards withdrawn for analysis.

Theoretical hydrogen–air (that is, $2H_2+O_2+3{\cdot}76N_2$) explosions went off quite normally up to an initial pressure (P_1) of 500 atmospheres, the 'explosion time', t_m, being of the order 0·015–0·022 sec., but tending to increase with the pressure. The subsequent rate of cooling accorded with Newton's law throughout, being uncomplicated by any appreciable exothermic effect; the amount of steam-dissociation at the maximum explosion temperature (T_m) was always less than 0·5 per cent. At $P_1 = 750$ atmospheres, however, such violent detonation was instantaneously set up that the screw threads of the bomb fittings were seriously damaged and it was deemed too dangerous to proceed to any higher pressure.

Explosions of theoretical carbon monoxide–air (that is, $2CO + O_2 + 3{\cdot}76N_2$) mixtures were successfully carried out at various initial pressures up to and including 1,000 atmospheres, with results showing that the nitrogen activation had reached a maximum at $P_1 = 350$ atmospheres, when its exothermic effect on the cooling curve was equivalent to some 12·5 per cent of the total kinetic energy developed. In explosions at $P_1 = 1{,}000$ atmospheres, $t_m = 0{\cdot}24$ sec., and the maximum gauge pressure (P_m) developed was 7,100 atmospheres (about 46 tons per sq. in.), with T_m just under 3000° K. The percentage dissociation of carbon dioxide at T_m ranged from 2·4 at $P_1 = 250$ up to 5·5 with $P_1 = 1{,}000$ atmospheres.

The $2CO + 3O_2 + 2N_2$ explosions (*b*) showed not only the beneficial influence of pressure upon the nitric oxide formation, but also that in all cases it begins during the 'combustion period' and extends far into the 'cooling period'. Thus, whereas at $P_1 = 70$ atmospheres only about 3·3 per cent of nitric oxide had been formed up to the moment of maximum pressure ($T_m = 2900°$ K.) as much as 5·4 per cent was present some 0·06 sec. thereafter; and at $P_1 = 88$ atmospheres the maximum nitric oxide formation would be of the order of 6 per cent. Such yields of nitric oxide are many times higher than any previously obtained in explosions.

Obituary

Prof. G. C. Bourne, F.R.S.

The death on March 8 of Gilbert Charles Bourne, emeritus professor of zoology and comparative anatomy in the University of Oxford, will be deplored by his colleagues and many friends in Oxford and elsewhere. The sudden ending of such a remarkably active and useful life will be felt as a serious loss.

Since 1919 and up to his last illness, Prof. Bourne had, with characteristic energy, taken a prominent part on the Advisory Committee on Fishery Research to the Development Commission of which he eventually became chairman, succeeding Sir William Hardy in 1931. The success of the Freshwater Sub-Committee, of which he was also chairman, owed much to his untiring labours, his wide knowledge of biology and his business ability. No less valuable were his services to the Water Pollution Research Board of the Department of Scientific and Industrial Research. Under his chairmanship of committees a thorough biological, chemical, and hydrographical survey of the River Tees was carried out and similar work undertaken on the Mersey.

Of a friendly, sanguine, and generous disposition, and actuated by a strong sense of public duty, Bourne was always ready to serve his country in peace or war. As a young man, he joined the Volunteers and the militia in which he rose to the rank of Lieutenant-Colonel (Hon. Colonel). During the War he was chiefly engaged in the training of recruits.

Bourne's fame as an oarsman and a rowing coach is known to all. His versatility was indeed remarkable. There were few practical things he could not do and do well. He seemed equally proficient with the oar or the marine trawl, the microscope or the sporting gun.

Born in 1861, the son of Lieut.-Col. Robert Bourne, of Cowarne Court, Herefordshire, he was educated at Eton and New College, Oxford. Always interested in natural history, he studied zoology under Prof. H. N. Moseley, worked for a short time with Prof. Weismann in Freiburg, and, after taking his degree, started on his scientific career. A description of the anatomy of the millipede, *Sphærotherium*, more especially of its stridulating organ, read before the Linnean Society in 1885, was his first publication.

In the same year Bourne visited Diego Garcia, that lonely tropical island set in the midst of the Indian Ocean. Here he studied corals, having joined that band of enthusiasts, including A. C. Haddon, S. J. Hickson, and G. H. Fowler, who did so much to advance knowledge of these and other cœlenterates. Diego Garcia is a typical coral atoll, and Bourne was among the first to treat atoll-formation not so much as a problem of geology as one to be attacked from the point of view of biology. His observations made on the spot of the conditions under which corals live and grow, flourish and decay, enabled him to contribute an important paper to the *Proceedings of the Royal Society* in 1888. Meanwhile, on his return, he had begun a series of papers on the structure and growth of various corals, of which those on *Fungia* (*Quart. J. Micro. Sci.*, 1887) and on *Heliopora* (*Phil. Trans.*, 1896) are perhaps the most outstanding. He was also interested in the Crustacea, wrote on *Monstrilla* and other copepods; and later made an elaborate study of crabs of the family Raninidæ, for which he founded the new tribe Gymnopleura (*J. Linn. Soc.*, 1922).

The translation of Pelseneer's masterly volume on the Mollusca for the "Treatise on Zoology", undertaken at Sir Ray Lankester's suggestion, turned Bourne's attention to new fields, and led to the appearance of several works on little-known molluscs, particularly on the Neritacea and other gastropods (*Proc. Zool. Soc.*, 1909, 1911). These various contributions on the structure and classification of the Invertebrata are all distinguished for care and thoroughness, and for the excellence of the illustrations; for he was a patient and skilful dissector and a very accurate draughtsman. Together they form a solid and lasting addition to zoological science.

Bourne's more general works include "An Introduction to the Study of the Comparative Anatomy of Animals", one of the best elementary textbooks of the kind when it first appeared in 1900, and still a useful and trustworthy guide for the student. To Lankester's well-known "Treatise on Zoology" he contributed comprehensive parts on the Ctenophora and on the Anthozoa, including, of course, his beloved corals.

Soon after taking his degree, Bourne was elected fellow of New College, and later became tutor as well. For a couple of years he went to Plymouth as director of the recently established Marine Biological Laboratory. On his return to Oxford he taught for many years in the Department of Zoology and Comparative Anatomy. In 1906 he succeeded Prof. Weldon in the Linacre chair, which he occupied with distinction until his resignation in 1921. He was elected to the fellowship of the Royal Society in 1910, and was president of Section D (Zoology) of the British Association at Sheffield in the same year.

Bourne married the daughter of Sir John Croft, Bt., who survives him with one son and one daughter. The former, Capt. R. Bourne, is now member of Parliament for Oxford. E. S. G.

We regret to announce the following deaths:

Sir John Jackson, O.B.E., deputy chief inspector of factories from 1920 until 1930, on March 19, aged sixty-eight years.

Dr. Thomas C. Porter, for many years science master at Eton College and one of the founders of the (Public Schools) Science Masters' Association, on March 31, aged seventy-three years.

News and Views

Nature of the Nerve Impulse

THE intimate nature of the nervous impulse has long been a subject for speculation by physiologists and psychologists. Simple models to explain the mode of transmission of an impulse along a nerve, like the electrical one of the marine telegraphic cable or like the chemical one of a train of gun-powder, have proved to be totally inadequate to explain the various phenomena observed in nerve. Until recently, the relative unfatiguability of nerve favoured a simple physical and non-chemical hypothesis. Modern refinements in technique, however, have shown that nerve during activity utilises chemical energy and produces heat. It is only in the last few years that the two phases of heat production in nerve have been analysed, and an account from the leading investigator in this field, Prof. A. V. Hill, appears in the special supplement to this week's issue of NATURE. Prof. Hill favours an electrochemical theory of a self-propagating wave of disturbance to explain the various forms of behaviour exhibited by an impulse in its passage along a nerve. Interesting experiments on the ionic distribution of potassium ions lend convincing support to the theory. The supplement will also be found to give a useful summing-up of the present position reached by investigators in this branch of nerve physiology.

Sir Charles Peers, C.B.E.

SIR CHARLES PEERS, Chief Inspector of Ancient Monuments and president of the Society of Antiquaries, has been awarded the Royal gold medal of the Royal Institute of British Architects for his services to architecture. The presentation took place at the Institute on April 3. Sir Charles Peers has now held office as Chief Inspector of Ancient Monuments for twenty years. It is largely owing to his zeal in carrying out his duties and the breadth of his practical knowledge in archæological matters that, not only have a large number of our antiquities been preserved from vandalism, but also the co-operation of the Office of Works, of which he is an officer, has been sought readily and with confidence by those who are interested either as owners, as archæologists, or as members of the public in the future as well as the past of ancient monuments. At the same time, the powers and duties of his office and his department, which were anything but adequate at the time of his appointment, have been enlarged by successive Acts of Parliament, until, with notable reservations to which attention has been directed with emphasis recently, such monuments are now within a measurable distance of a reasonable assurance of safety.

Trevithick Centenary Exhibition

IN connexion with the celebration of the centenary of the death of the great Cornish engineer and inventor Richard Trevithick, the 'father' of the steam locomotive, a memorial exhibition has been arranged in the main gallery of the Science Museum, South Kensington. Trevithick was an inventor of astonishing fertility but his main contribution to engineering progress was his invention of the high-pressure non-condensing steam engine and its application to both road and rail locomotives. His outstanding patent was taken out in 1802, and engines were made all over England to his designs. Of these engines two excellent specimens are shown, one with a cast iron boiler, made in 1805, and another made in 1811 with a wrought iron boiler. Unfortunately, nothing remains of his several locomotives, but various documents and drawings are exhibited and there are also some of the cast iron rails from Penydarran, South Wales, on which his first locomotive ran. This engine, the first rail locomotive in the world, is known to have drawn five wagons with a load of ten tons in 1804, and four years later Trevithick exhibited a locomotive, afterwards named *Catch-me-who-can*, "in the fields adjoining the Bedford Nursery near Tottenham Court Road", London. The next locomotive of importance was that constructed by Matthew Murray for John Blenkinsop at Leeds in 1811, but the original drawings for this were supplied by Trevithick, who received a royalty on the engine. The exhibition also includes Linnell's portrait of Trevithick painted in 1816, Burnard's bust and many interesting letters and documents.

Memorial to Thomas Tompion

ON Saturday, April 1, a plaque in memory of Thomas Tompion, the clockmaker, was unveiled in St. Mary's Church, Northill, Bedfordshire, where he was born in 1639, and simultaneously a wreath was laid on his tomb in Westminster Abbey, where he was buried in 1713. The plaque is the gift of the Clockmakers' Company and was unveiled by the Master, Mr. B. Kettle, the address at the service being delivered by the Archdeacon of St. Albans, the Ven. A. H. Parnell. At the ceremony at the Abbey, Sir Francis Newbolt, the Deputy Master of the Clockmakers' Company, said Tompion was honoured by the Company as one of its greatest Masters. So great was his mechanical genius and incessant industry that he was appointed clockmaker to the Royal Observatory at Greenwich at its foundation. He was a brilliant craftsman and made practical the theoretical inventions of others. He left English watches and clocks the finest in the world and the admiration of his brother artists. The grave Tompion lies in, it may be remarked, also contains the remains of his famous pupil and successor, George Graham, who died in 1751. The slab now to be seen in the Abbey, on which Graham's remarkable skill is referred to, was removed in 1838 and a small lozenge-shaped stone substituted. Thanks, however, to Dean Stanley, the original was replaced in 1866.

Centenary of Maurice Loewy

ON April 15 occurs the centenary of the birth of the distinguished astronomer, Maurice Loewy, who, from 1896 until 1907, held the directorship of the

Paris Observatory, a post to which he was appointed on the death of Felix Tisserand. Born in Vienna in 1833 of Jewish parents, Loewy passed through the Polytechnic School and University of Vienna and then entered the old Imperial Observatory of the capital, where he was trained by Karl Littrow. Being invited to France by Le Verrier, he became a naturalised Frenchman and in 1864 joined the staff of the Paris Observatory, serving under Le Verrier, Delaunay, Mouchez and Tisserand. He took an active part in the completion of the great Paris Catalogue of Stars and in the inauguration of the International Star Chart. So early as 1871 he proposed to Delaunay the new form of telescope since known as the equatorial *coudé*, but it was not until 1882 that the first instrument of this kind was erected, the cost of the telescope then being defrayed by the generous banker Raphael Bischoffsheim (1823–1906), the founder of the Nice Observatory. A description of the instrument appeared in NATURE of November 8, 1883, p. 36. For thirty years Loewy was director of the *Connaissance des Temps*, and from 1872 was a member of the Bureau des Longitudes, taking part with Mouchez in the inauguration of the observatory in the Parc de Montsouris for the instruction of navigators and explorers. From 1873 onwards he was also a member of the Academy of Sciences. He received many honours from learned societies and in 1889 was awarded the gold medal of the Royal Astronomical Society. He died suddenly on October 15, 1907, at the age of seventy-four years, when addressing a meeting of the Conseil des Observatoires astronomiques.

Priestley Bicentenary Celebrations at Warrington

WHEN non-conformists were debarred from studying at Oxford and Cambridge, a number of dissenting colleges came into existence, among the most famous and successful of which was the Warrington Academy, through which, during its existence from 1757 until 1783, some four hundred pupils passed. It was in this Academy that Priestley taught from 1762 until 1767, and it was there he wrote his "History of Electricity". In 1898 the Warrington Society was formed with the object of preserving the building which originally housed the Academy, and to-day it possesses an interesting collection of Priestley pictures, books and medallions. In conjunction with the Warrington Philomathic Society, therefore, it held a Priestley commemoration meeting in The Old Academy on March 17, when the Priestley relics were shown to visitors and two addresses were given, the first being by Mr. J. Hawthorn on "Joseph Priestley and Warrington" and the second by J. S. Broome on "Priestley's Scientific Work in Warrington". When Priestley was offered a post at the Academy, he followed Dr. Taylor as tutor in languages although, as he himself wrote, "I should have preferred the office of teaching the mathematics and natural philosophy, for which, I had at that time a great predilection". In spite, however, of being employed five hours a day in lecturing on English, Latin, Hebrew and other subjects, he yet found time to make experiments and carry on a correspondence with Franklin, and it was his scientific work at Warrington which led to his being admitted to the fellowship of the Royal Society.

Stereochemistry and Physics

THE Faraday lecture of the Chemical Society was delivered at the Royal Institution on March 29 by Prof. Peter Debye, of the University of Leipzig. He took as his subject "The Relations between Stereochemistry and Physics" and gave a brilliant exposition of certain methods used for the elucidation of molecular shape and dimensions, methods to which his own contributions, both in theory and in experimental technique, have been all-important. Until comparatively recently, the two factors which essentially determine the dielectric constant of a substance were not clearly distinguished from one another. Prof. Debye showed how the total polarisation in an electric field is compounded of the natural polarisation inherent in the molecules themselves and of an induced polarisation, due to their electrical deformability; how the relative contributions of these two effects can be estimated by investigating the influence of temperature on dielectric constant; and how the magnitude of the natural dipole moment thus obtained can give valuable information on the degree and the nature of symmetry of the molecule. Examples were quoted from the work of Errera, Smyth and Williams.

IN the latter half of the lecture, Prof. Debye dealt with his pioneer investigations on X-ray interference patterns produced by isolated molecules, describing the technique, the application of the numerous necessary corrections to the experimental data, and the interpretation of the latter in terms of the interatomic distances in the molecule. Mention was made of the related electron ray method of Mark and Wierl. He illustrated his fascinating topic by reference to work on the chlorine substitution products of methane, and to the problem of free rotation of single bonds. The interest and enjoyment of his hearers were obvious. One may indeed be excused for thinking that very seldom are occasion and lecturer, theme and audience so completely attuned to one another as happened at this lecture. Prof. Debye had no difficulty in establishing Faraday as a pioneer of ideas in the fields both of the electrical properties of molecules and of the spatial arrangement of atoms within them. All felt that Sir William Bragg was right when he claimed that Prof. Debye and Faraday were akin in spirit; Prof. Donnan was equally right when he termed Prof. Debye the friend of the chemist, of the "hydrophobic organic chemist equally with the hydrophilic physical chemist".

The Chemical Society

PROF. G. G. HENDERSON, the retiring president of the Chemical Society, devoted his presidential address on March 30 to an examination of the present position and the future of the Society. Scientific societies, he said, must be ready to modify their policies in accordance with changing conditions. The work of the Chemical Society in pursuing the objects for which it was founded has increased during the past year, and the work of the Bureau of Chemical Abstracts also reflects the ever-increasing amount of investigation which is being performed in the chemical field. New decisions which will help to meet modern needs include devoting a larger number of meetings to organised discussions and summaries of recent work, offering fellowship to young chemists at half the annual subscription, selecting the papers to be read at ordinary scientific meetings, arranging that some of the endowed and special lectures shall be delivered elsewhere than in London, and appointing local representatives who will arrange lectures or discussions in collaboration with the local secretaries of other chemical organisations, and will generally promote the interests of the Society. The Council does not contemplate the establishment of local sections of the Society, since numerous local sections of the Institute of Chemistry, the Society of Chemical Industry, and of other societies are already in existence.

Federation of Chemical Societies

PROF. HENDERSON also referred to the new format of the *Journal* of the Society, and remarked : "I trust that the combined effort of the Chemical Society and the Faraday Society to produce a joint publication, which is destined to be the representative journal of British physical chemistry, will be brought to a successful issue, and that the new journal will appear next year". New conditions have created new wants, and he feels that new methods with respect to administration, to the representation of fellows in the Council, to the production and distribution of publications, and to the association of the Society with other chemical organisations must be adopted. Federation or union of at least all the principal organisations concerned with chemistry, said Prof. Henderson, is a project which is making an appeal to an increasing number of members of the profession. Prof. Henderson referred to an article on the subject in NATURE of September 24, 1932, and quoted the conclusions, saying that they well summarise the facts which compel attention to this matter. "So long as the Society remains, as now, an independent organisation," he said, "I cannot see how a larger income is to be obtained . . . and every method of reducing expenditure which can be adopted under existing conditions has been closely investigated. The same statement applies generally to the Society of Chemical Industry, the Biochemical Society, the Faraday Society, and other societies more directly interested in various branches of applied chemistry, which publish journals or abstracts or both. Consequently one is forced to the conclusion that some form of federation of these societies is not only desirable, but sooner or later inevitable. Moreover in my opinion such a federation would be incomplete and lacking in influence unless the professional organisations were also included as members."

THE kind of federation which Prof. Henderson envisages would not involve material loss of individuality on the part of the members of the separate societies, for each has its special sphere of activity on behalf of the subject as a whole and of the profession generally. The final decision must rest with the members of the organisations concerned, but Prof. Henderson said he is confident that if chemists of all kinds got together in some such way as he had indicated, the effect would be altogether beneficial to the profession. He believes that the movement, if generally supported, would be welcomed by the chemical industry of the country. Sympathetic consideration must be given to the scheme to be put forward by the Federal Council for Chemistry, which has appointed a committee to frame proposals calculated to afford the chemical societies of Great Britain means of securing economies, increased efficiency, and mutual advantage.

Houston Expedition over Everest

THE Houston Air Expedition to Mount Everest succeeded in its object to fly over the actual peak on the morning of April 3. The flight, starting from Lalbalu aerodrome, occupied three hours, flew about 160 miles including two circuits of the peak, reached more than 31,000 ft. altitude, and actually cleared the top by only 100 ft. The two machines, a Houston-Westland and a Westland-Wallace (Bristol Pegasus S.III engines), flew in company and carried out a concerted programme of duties. The decision to make the flight was taken on the advice of the Indian Government Meteorological Station at Purnea, which reported winds of 57 m.p.h. velocity, without undue bumpiness, at 33,000 ft. altitude, by means of the usual balloon observations. Air-Commodore Fellowes, the leader, made a preliminary reconnaissance in his Puss Moth machine before making the final decision to start.

CONSIDERABLE credit is due to the crews of the Houston Expedition for their navigation, as it was impossible to adhere to the prepared scheme of observations from landmarks owing to a heavy dust haze extending up to 19,000 ft. They also met with severe down currents due to the deflection of the west wind over the mountain, causing a loss of altitude of more than 1,500 ft. in a few seconds in one case. Very good still photographs were obtained, but the results of the cinema cameras are not yet known. The automatic survey cameras were not working during part of the flight, which may mean that necessary connecting parts of the mosaic survey may be missing. In this event a further flight will be made if permission can be obtained from Nepal. The unusual clearness of the air made it difficult for the photographers to judge distances accurately. The crews were afterwards examined by the expedition's doctor, who found that they were tired, but not unduly exhausted. On April 4, a further flight was made by both machines over Kanchenjunga.

Loss of the *Akron*

WE much regret to record the total loss of the United States naval airship *Akron*, which occurred on April 4. It appears that the vessel left Lakehurst for a cruise over the coast of New England on April 3 in order to test her wireless compasses. A wireless message during the evening reported that all was well and nothing further was heard until a German tanker, the *Phœbus*, reported by wireless that the *Akron* had 'crushed' at sea and that four of the crew had been picked up, one of whom died later. One of the survivors is Lieut.-Comdr. H. Wiley, the second-in-command, who has recovered sufficiently to make a report on the disaster. The airship sighted a thunderstorm at 8.45 p.m.; later, the ship at 1,600 ft. appeared to be surrounded by lightning and about midnight she began to descend rapidly. Ballast was thrown out and she regained altitude, only to descend again a few minutes later. The rudder control was carried away as the airship crashed and it seems that the main part of the ship sunk almost immediately. The *Akron* was the largest airship in the world, her gasbags were filled with helium, and, at the time of the disaster, there were seventy-seven officers and men aboard, including Rear-Admiral William Moffett, chief of the U.S. Naval Bureau of Aeronautics. Rescue work was hampered by the weather, and a 'blimp' returning from a search for survivors was blown into the sea on attempting to land, one of the crew being drowned and the commander dying shortly afterwards. Yet another airship accident has been reported, this time from France, where the semi-rigid naval dirigible E9, crashed near Guerande on April 4, two of the crew of twelve being injured.

Science at the Ideal Home Exhibition

THE *Daily Mail* Ideal Home exhibition at Olympia, which was opened by Mrs. Stanley Baldwin on March 29 and will remain open until April 29, is, as usual, a remarkable tribute to the influence science now exerts on the equipment of up-to-date houses. Thanks to the use of gas and electricity, the investigations of the chemist, physicist and metallurgist, the duties of every housewife are steadily being lightened and the comfort and convenience of everyone increased. The gradual improvement in the quality of food and in its preparation, and in all connected with lighting, heating and ventilation is indeed remarkable. New metals, new materials and new designs, and the application of scientific methods are seen on every hand. The exhibition occupies the Grand Hall, the National Hall and the Empire Hall, and in the first of these is an admirable and beautiful scheme of decoration which includes, as its outstanding feature, a portion of an immense rainbow composed of no less than 700 ft. of neon tubes, fitted up by Messrs. Venreco, Ltd.

WITHOUT attempting to refer to the many exhibits which owe so much to scientific research, attention may be directed to the interesting series of "Rooms of the Scientists" in the gallery of the Empire Hall, where "for the first time in history, are gathered together a collection of exhibits more romantic than any story, more sensational in their results than the wildest fiction". There are nine of these rooms showing respectively Archimedes in his villa at Syracuse; Roger Bacon in prison; Newton in his study at Cambridge making his experiment on light; a part of the surgical ward at the Glasgow Royal Infirmary where Lister did his important work during 1861–69; the tent of Sir Ronald Ross in which he made his observations on the relation of the mosquito to malaria; Darwin's study at Down House in which he wrote "The Origin of Species"; a replica of Prof. Piccard's sphere in which he made his record ascent into the air; Faraday's laboratory at the Royal Institution; and lastly, the wireless cabin of the Marchese Marconi on his yacht *Elettra*. The tableaux are admirably arranged and the eminent men of science are represented by members of the theatrical profession, that of Newton, for example, being played by Mr. Rodney Barrie. The whole exhibit has been staged by Prof. A. M. Low for *Armchair Science*, with the assistance of many scientific bodies and individuals, including the British Museum, the Science Museum and the Royal Institution.

Bequests for Geological Research

MR. BERNARD HOBSON, of Sheffield, who died on December 3, left estate of the net value of £142,125. He bequeathed £1,000 to the Yorkshire Geological Society, Leeds; £1,000 to the Geological Society of London, to be called the "Bernard Hobson Fund", the annual income of which is to be used in buying British, Colonial and foreign geological maps, to be placed on linen conveniently folded for the pocket for use of the members of the Society; and £1,000 to the British Association for the Advancement of Science, to be called the "Bernard Hobson Fund", the annual income of which is to be devoted to promoting definite geological research. After making further bequests totalling about £3,000, Mr. Hobson left the residue of his estate to his brother and sister for life, with remainder to the University of Sheffield. Mr. Hobson had been a member of the Council of the University for some years. He belonged to a family which had taken a special interest in it. His father, Mr. John Hobson, was a member of the Council of Firth College, from which the University sprang. His brother, the late Sir Albert Hobson, as Master Cutler in 1903, took a leading part in the movement for the establishment of the University, and served successively as Treasurer of the University and Pro-Chancellor. Sir Albert, who died in 1923, also left the residue of his estate to the University.

Research Grant for the Cancer Hospital (Free), London

RECENTLY the investigations on the chemical aspects of the cancer problem which are in progress at the Research Institute of The Cancer Hospital (Free), Fulham Road, London, have received recognition and financial assistance from two sources. The trustees of the Halley Stewart Trust have made a grant for a period of three years to support a whole-time worker who will undertake biochemical investigations into the metabolism of cancerous growths. Dr. C. A. Mawson of the Victoria University of Manchester has been appointed to carry out this work.

No. 3310 APRIL 8, 1933

The Physical Nature of the Nerve Impulse*

By PROF. A. V. HILL, O.B.E., F.R.S.

ALL our sensations, all our movements, most of the activities of our nervous system, depend upon a certain transmitted disturbance which we call the nervous impulse: this, in the study of nerve activity, is what the atom, the electron and the quantum are to chemistry and physics. A rapid reaction to events occurring at a distance is necessary for efficient working. Special nerve cells, therefore, have been developed in all the larger animals: from these the axon or nerve fibre runs out, which is only 3 μ to 25 μ in diameter but may be many metres in length. Along these fibres wave-like messages are sent.

The velocity of a nerve impulse varies greatly according to the fibre in which it runs and to the conditions affecting the fibre. In the medullated nerve of a mammal the velocity is of the order of 100 metres per second. (Compare this with 330 metres per second, the velocity of sound.) In the medullated nerve of the frog at 20° C. it is about 30 metres per second. In the non-medullated nerve of a mammal it is said to be about one metre per second; in the non-medullated nerve of the pike and of *Anodon* respectively it is stated to be 0·2 metre and 0·05 metre per second. The velocities in this list are in the ratio of 2,000 to 1.

The nerve impulse is an event, a wave, a propagated disturbance, not a substance or a form of energy. It is transmitted along a thread of protoplasm which, in medullated nerve, is surrounded by a protecting or 'insulating' sheath. Its passage can be detected in several ways: (*a*) by its physiological effect on the organ to which it runs, (*b*) by the electric change which accompanies its transmission, (*c*) by a production of heat, and (*d*) by a consumption of oxygen and a liberation of carbon dioxide.

No difference of electrical potential can be detected in an uninjured resting nerve. If, however, the nerve be injured, for example, by cutting, a potential difference is found of the order of a few hundredths of a volt between the injured and the uninjured parts, in the sense that positive current runs in an external circuit towards the former. The injury does not *produce* the potential difference; it merely allows its normal presence across the fibre boundary to be manifested.

If two electrodes be placed on a nerve and the nerve be stimulated, a momentary change of potential travels along it which can be recorded with an oscillograph. At any given instant a certain length of the nerve of the order of a few centimetres is found to be the site of a wave of negative potential. We are probably right in thinking that the impulse itself, whatever that be, occupies the same region and moves at the same speed as its electrical accompaniment.

PROPERTIES OF THE NERVE IMPULSE

Let us consider the properties of the impulse which is transmitted, or transmits itself, in nerve. The single impulse in the single fibre is the basis of nerve activity. Until recently, this individual impulse could not be separately examined and deductions had to be made from the results of stimulating many fibres in parallel. Of late, however, through improvements in electrical recording, it has become possible to register the form and movement of the electric change resulting from a single impulse in a single fibre.

(*A*) A single impulse has an 'all-or-none' character. Its size cannot be varied by changing the strength of the stimulus which produces it: it makes no difference to the magnitude of the discharge how hard the trigger is pulled. (*B*) An absolute 'refractory' period follows the passage of an impulse, a period during which no stimulus, however strong, can evoke a second response. In frog's nerve at 20° C. this absolute refractory period is about 0·001 sec. (*C*) As a consequence of (*B*), two nerve impulses going in opposite directions in the same fibre come each into the refractory region of the other and both are abolished. 'One way traffic' alone is possible: separate sensory and motor systems are required. (*D*) After the absolutely refractory stage a relatively refractory stage persists, during which a stronger stimulus than usual is required to start an impulse, and the second impulse, measured by electric change or heat, is smaller than the first one. Discharge can take place before recharge is complete. (*E*) As a result of the refractory phase, the frequency of transmission is limited. Prof. H. S. Gasser of New York recently informed me that he had made mammalian nerve carry 1,500 impulses per second, and that at 1,000 per sec., impulses were not greatly subnormal. In the normal functioning of the nervous system nearly all messages consist of trains of impulses of varying frequency. (*F*) The impulse at any instant occupies a few centimetres of the fibre. This length is not much altered by a change of temperature and it is approximately proportional to the diameter of the fibre. There must be some simple physical reason for these facts, as also for the next one. (*G*) The velocity of the impulse is also approximately proportional to the diameter of the fibre. Consequently in a given nerve trunk which consists of fibres of various diameters, a wave started electrically at one end gradually spreads out and appears as a series of waves corresponding to the several maxima in a frequency curve. (*H*) When the temperature is raised or lowered by 10° C. the velocity of transmission is increased or diminished in the ratio of 1·7 to 1. (*I*) The passage of an impulse is associated with a liberation of heat to which some special attention is necessary.

---

* Friday evening discourse delivered at the Royal Institution on Feb. 10.

HEAT PRODUCTION OF NERVE

No work is performed, no force is developed, no movement at all occurs in a nerve when it is active, and for long it was believed that in the transmission of nerve impulses no heat is evolved. Many attempts were made to measure the heat, all unsuccessful until 1925. To-day, when the heat production of nerve can be measured almost as well as that of muscle could in 1920, it is hard to believe that for many years we argued as though there was no heat at all associated with nerve activity. It is true that the amount is small, that the *total* heat (which takes thirty to fifty minutes to appear) in a single impulse in a gram of nerve is only about one millionth of a calorie, and it is true still that we must have several impulses before we can measure the heat properly, but with that provision and with present-day arrangements, the measurement is comparatively simple and accurate. The sensitivity is such (i) that a galvanometer deflection of 1 mm. (readable to 0·1 mm.) corresponds to a rise of temperature of about three millionths of a degree, and (ii) that during a steady state of heat production one millimetre of steady deflection corresponds to a rate of heat production of about 2×10^{-8} calorie per second.

The heat is produced not only during the passage of the impulse *but for a long time afterwards;* some kind of breakdown occurs, presumably as the wave goes by. This breakdown has then to be reversed, the nerve allowed to recover, in a re-charging process of some kind which takes place afterwards. The fact that heat is produced, and the manner of its production, dispose of the possibility that the nerve impulse is, to use Bayliss's words, a "reversible physico-chemical process".

At 20° C. the initial heat in a single isolated impulse in a frog's medullated nerve lies between 10^{-7} calorie and 3×10^{-6} calorie per gram of nerve. The recovery heat, which continues for a long time after the impulse has passed, is about ten to thirty times as much. During continual stimulation, say of fifty shocks per second, a steady state is gradually reached in which recovery balances breakdown, the recovery heat in any given interval representing the process of restoration from all the impulses which passed in the preceding forty minutes. During the steady state, which is possible only in oxygen, the total heat production may occur at the rate of about 25 microcalories per gram per second. At a higher frequency the total heat rate may, for a time, be rather greater, but a genuine steady state is not possible; fatigue progressively sets in. It is striking that the *resting* rate of heat production of the same nerve is about 70×10^{-6} calorie per gram of nerve per second, so that moderate activity only increases the metabolism of a nerve by a comparatively small amount, even extreme activity does not double it. The mere maintenance of the machine in working order requires more energy than the excess required when it goes full speed during activity.

This initial heat is the result presumably of some chemical reaction involved in, or immediately after, the transmission of the impulse. If we suppose the reaction to occur throughout the substance of the axis cylinder, its heat is so small that it is difficult to picture any mechanism by which the change could be propagated. There are other grounds—for example, the relation between speed and diameter—for supposing that the reaction, whatever it be, is somehow connected with the surface of the fibres. It can be calculated that the area of the surface in a gram of nerve is of the order of 2,000 sq. cm., and that the energy in the transmission of a single effective impulse is from 5×10^{-3} to $2 \cdot 5 \times 10^{-4}$ erg per sq. cm. of fibre surface. This is still a very small quantity, the smallness of which can be realised by the statement that it is 1/4,000 to 1/80,000 of the surface energy of a water–olive oil interface.

One naturally asks, may not the initial heat be really due to the electrical disturbance transmitted in nerve? If we take the observed potential differences along the nerve and assume that these cause currents to flow through the conducting media inside and outside the sheath, then the Joule's heat of the currents can be calculated. The result is only a small fraction, less than one per cent, of the observed initial heat. There is another possibility, however, namely, that the nerve is to be regarded as a charged electrical condenser which is discharged as the wave passes by. The energy of a condenser of capacity F microfarads, charged to V volts, is $5FV^2$ ergs. Taking V as 0·05 we should require a capacity of the order of half a microfarad per square centimetre of nerve fibre surface to give us the observed initial heat. There is some evidence that capacities of this size may possibly exist at the surface of living cells. If so, we should not need to look for a chemical reaction to explain the initial heat—

the electrical discharge would be sufficient. Other evidence, however, makes it unlikely that this is really the source of the heat.

The recovery process by which the nerve is restored to its initial condition is of an oxidative nature, though deprival of oxygen does not immediately cause it to fail. Apparently the nerve possesses, maybe as a safeguard against asphyxiation, a store of oxygen in some form other than molecular. A nerve may go on functioning and carrying out its usual recovery for hours, or even days (depending on the temperature) before all its oxygen store is used up. Then, and only then, it fails. If a nerve asphyxiated by lack of oxygen is given oxygen once more, recovery rapidly occurs and excitability returns.

OTHER EFFECTS OF OXYGEN

The difference of potential between an injured and an uninjured point of a crab's nerve is maintained for a long time in the presence of oxygen and the absence of stimulation. Stimulation rapidly reduces it, so to speak 'depolarises' the nerve surface. The potential rises again to its full value if, and only if, oxygen be present. In the absence of oxygen it falls still further. The potential difference across the surface of a nerve depends for its maintenance on the continued presence of oxygen.

Stimulation and lack of oxygen, however, are not the only means by which the potential difference can be reduced. There is normally a ratio of about 10 to 1 between the inside and the outside of a crab's nerve fibre in respect of potassium ion concentration. If we suppose that potassium is the only substance capable of penetrating the fibre surface of the crab's nerve, then this concentration ratio should lead to a potential difference of $\frac{RT}{F}\log_e 10$ which is about 58 mv. Values of 30 mv. in freshly dissected nerve are commonly observed, and sometimes more, and since a certain amount of short-circuiting must occur in the strongly conducting fluid between the fibres, the real value may well approximate to the 58 mv. required by the formula. If the hypothesis is right, the potential difference would be reduced by increasing the potassium ion concentration on the outside of the fibre. Cowan has found this to be the case. By soaking a nerve for a few seconds in sea-water to which potassium has been added, the potential difference may be varied from 30 mv. or 40 mv. down to nearly nothing as desired. The potential difference is clearly determined by the potassium ion concentration, and yet it is dependent also on the presence of oxygen. This paradoxical dependence on two such different factors has not yet been resolved: perhaps the oxygen is used in maintaining the normal properties of the surface membrane.

Another, and a most curious effect of oxygen, has recently been observed in the action of veratrine, a plant alkaloid, on frog's nerve. Applied to a muscle, this drug causes a prolonged response to a single impulse: applied to a nerve it has little effect, the action current is not greatly lengthened, the heat production is not largely increased, by soaking the frog's nerve for an hour in 1 in 50,000 veratrine solution. If, however, after the nerve has been soaked it be then asphyxiated for three or four hours until it is completely inexcitable, and if it be then revived by admitting oxygen, it shows in a striking manner a typical veratrine effect. The action current lasts hundreds of times as long, the heat production is thousands of times as great, as in the normal response of a nerve to a single shock.

Apparently the drug is usually unable to penetrate the nerve fibre sheath. When, however, the nerve has been asphyxiated, the condition of the surface has somehow been altered so that the substance which was previously held out is now able to penetrate. Oxygen is necessary for the maintenance of the normal impenetrable condition of the surface of the fibre. One naturally associated this effect with the presence of a thick sheath around the axis cylinder, and asked whether the veratrine effect could be manifested in other nerves in which no medullary sheath is present. The experiment was made by Cowan, and showed that in crab's nerve a typical veratrine effect is produced without any asphyxiation, and that the concentration of the drug required is only one thousandth of that for frog's nerve. Veratrine apparently can penetrate normally the very thin surface of a non-medullated nerve, but it is held out almost indefinitely, until the nerve is asphyxiated, by the sheath normally covering the axis cylinder of a medullated nerve.

This strange result suggested that the effect of curare should be similarly tested. Curare paralyses a muscle, in respect of impulses coming to it along its motor nerve. It was formerly thought to attack the neuro-muscular junction, though recently, on the strength of Lapicque's theories, it has been supposed to produce its effect by changing the 'time scale of excitation' of the muscle fibre, putting it out of tune so to speak with its nerve. Recent work by Rushton has shown that this hypothesis of Lapicque's is untenable, so that the manner of action of the drug was still unsolved. It was possible that curare might be a potent nerve poison but normally unable to penetrate except at the neuro-muscular junction. At this point the medullary sheath is absent. Perhaps a nerve dosed with curare but apparently unaffected, might be found effectively poisoned after asphyxiation.

The experiment was performed by Fromherz: a muscle nerve preparation was paralysed by soaking in curare, the nerve was removed and still showed a normal action current: it was then asphyxiated in hydrogen and after asphyxiation allowed to recover (if it could) in oxygen. An unpoisoned nerve treated in this way immediately gives a large action current on readmission of oxygen. The curarised nerve gave only a small one and recovered very slowly. Curare, therefore, may render a nerve incapable of responding, once it is able—as during a state of asphyxia—to get in. This may be the solution of the problem: the effect of curare is not on the 'chronaxie' of muscle, but on the part of the nerve which is exposed to the action of the drug, namely, its ending where the medullary sheath is absent.

TIME RELATIONS OF EXCITATION

All living animals, organs, or organisms, have a certain characteristic scale of time. The fibres of the wing muscle of a fly can contract hundreds of times a second, those of the leg muscle of the tortoise, differing from the fly's in no other very obvious way, may take several seconds to give a single twitch. The mouse and the man differ greatly in many of their characters and the difference is largely that of the scale of time on which respectively they live. This difference of time scale is a necessary accompaniment of a difference of size: a very small motor may do 10,000 revolutions per minute, a large one must be content with a few hundreds. One of the most important problems of physiology, and it is a problem of general, almost of philosophical interest, is what determines the scale of time of an animal or cell.

In nerve, the time required at any point for the action current to go through its cycle, the time taken in the transmission of the impulse, and the time-scale (to which I will refer later) of electric excitation, all can be varied together as we alter the condition of the cell or pass from one cell to another. These are different aspects of the same phenomenon—the transmission of the impulse. At the end of the last century it was shown by Waller, employing stimulation by condenser discharge, that there is an 'optimal' stimulus for any given tissue, in the sense that the energy in it is a minimum. He showed, and Keith Lucas following him showed, that the effectiveness of a condenser stimulus of given energy depends upon the rate of discharge of the condenser. If F be the capacity and R the resistance through which discharge takes place, the time of discharge is proportional to the product FR, and for given energy $\frac{1}{2}FV^2$ in the stimulus, the response depends on the product FR.

The use of condensers is very convenient and is generally adopted in studying the time relations of the excitatory process. The relation, however, is clearer if excitation be produced with the aid of a constant current of variable duration. If a constant current be led into an excitable tissue by two non-polarisable electrodes, in order that a stimulus of very short duration may be effective its intensity must be great, while if it lasts for a long time its intensity may be small. In the case of medullated nerve the times involved are very short, so that rather special methods of determining the duration of the constant current employed must be adopted. The relation between the duration of a constant current and the least strength required for excitation (the so-called strength-duration curve) is shown in Fig. 1.

In the case of nerve this curve is always approximately of the same form and may be defined by two parameters, the scale of time and the scale of current. The latter is of no particular interest, since most of the current is short-circuited in the fluids between the excitable elements and no strictly standard conditions for comparison can be defined. The scale of time, however, *is* important, and is very constant for a given nerve under given conditions, and the usual method of expressing it is by means of the minimum duration of a current of twice the threshold strength. This duration was called by Keith Lucas the 'excitation time' and by Lapicque the 'chronaxie', the latter term in its derivation meaning no more than the time scale of the process or tissue in question.

The excitation time of nerve depends upon many factors: (*a*) the nature of the nerve itself; it varies greatly from one fibre to another, in the same kind of way as the velocity of propagation of the impulse referred to earlier; (*b*) it is increased by a fall, decreased by a rise of temperature; (*c*) it is considerably affected by the nature of the ionic constituents in the solution around the nerve, particularly by the concentration of the calcium, and to a less extent of the potassium ion; (*d*) it depends upon the size of the fibre, being smaller in a fibre of greater diameter.

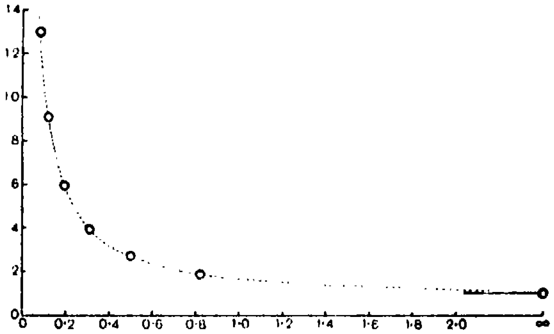

FIG. 1.

"Strength duration curve" for nerve excitation. Horizontally, duration in σ (0·001 sec.): vertically, minimum strength required.—From "Chemical Wave Transmission in Nerve", by A. V. Hill (Cambridge University Press, 1932).

The form of the strength-duration curve leads us to a discussion of the nature of electrical excitation. A constant current passed through an excitable tissue excites twice, once at the cathode at make, once at the anode at break. Unless the current be too strong, when secondary effects (for example, electrolysis and polarisation) occur, no propagated impulse is started off during the passage of a constant current. With an alternating current, however, of not too high a frequency the case is different. An impulse starts off from the cathode for each positive phase of the current, another from the anode for each negative phase. This is true up to, say, 300 a second for a frog's nerve, 700 a second for a mammalian nerve. When, however, we consider the case of a much higher frequency, say, of 100,000 to 1,000,000 per second, a different result is found. Such currents produce no response even though they be so strong that considerable warming occurs. This is commonly imagined to be due to the so-called 'skin effect', but it can readily be shown that with the high specific resistance of living tissues the skin effect does not come in until a frequency is reached far higher than that we are considering.

Let us suppose that excitation occurs, that an impulse is started, when the current outwards through the sheath of a nerve fibre in the region of the cathode attains more than a certain density (Fig. 2). When the outward current is large enough something is rendered unstable, and the state of instability is propagated as a wave. We suppose that the sheath of a fibre possesses the properties of a dielectric of high but not infinite specific resistance. The first effect of a difference of potential applied along the nerve is to charge the capacities at the anode and the cathode. The nerve, in fact, acts like a cylindrical condenser, the sheath being the dielectric between the plates.

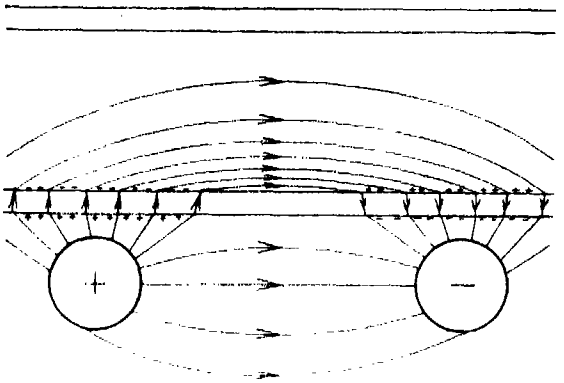

FIG. 2.
Nerve fibre with two electrodes; current flow outside, inside and through sheath.

When an alternating current of high frequency is applied between electrodes resting on the nerve the effect of each cycle is to charge, alternately in opposite directions, the condensers lying near the electrodes. Unless the current be very strong, these condensers absorb it and prevent a potential difference from arising across the dielectric of sufficient intensity to drive any considerable current through the latter. With a lower frequency, however, or with a constant current, while the first effect is still to charge the condensers, as these are charged a difference of potential arises across the dielectric by which a current is caused to pass. When this current reaches a sufficiently high density outwards at the cathode, instability is produced and excitation occurs.

With constant currents, the shorter the duration, the greater the current has to be to produce an excitatory effect. With a current of great duration the capacities in the surface of the fibre have ultimately no influence. With very short durations, however, the first effect is to charge the condensers and so to reduce the E.M.F.'s available across the dielectric. If then the applied current is cut off before the condensers are charged, the potential difference across it will be less than that which would ultimately be attained, and for excitation to occur the applied E.M.F. must be greater.

From this model an equation for the strength-duration curve can be deduced as follows:

$$C = \frac{R}{1 - e^{-t\Big/\frac{Fr\,(r_o + r_i)}{2r + r_o + r_i}}}$$

Here C is the current, t its duration, R a constant, F the capacity and r the resistance per sq. cm. of the sheath in the neighbourhood of the electrodes, r_i the resistance of the inside, r_o that of the fluids on the outside, of the nerve between the electrodes.

For the case of electrodes very far apart where $(r_o + r_i)$ is large compared with r, this equation approximates to

$$C = \frac{R}{1 - e^{-t/Fr}}$$

The important term in deciding the form of the relation is the product Fr, which is obtained by multiplying together the capacity and the resistance per square centimetre of the surface of the fibre. The relation experimentally observed in the strength-duration curve (Fig. 1) is fitted with sufficient accuracy by this equation.

If the excitation time be determined by the product of the capacity and the resistance per square centimetre of nerve fibre surface, then we should seek to explain the differences between different fibres, or between the same fibre under different conditions, by changes in the product Fr. The thinner the sheath the greater will F be, and the greater the excitation time: the lower the resistance, the shorter will be the excitation time. A rise of temperature presumably alters the excitation time by diminishing r. The absence of calcium causes a large increase in the excitation time, possibly through an increase in the resistance of the surface of the nerve. Such a change of resistance might be brought about by an alteration in the state of the emulsion of oil in water, or water in oil, of which it is possible that the sheath of the nerve is composed.

There are complications, however, in this story. It seems certain that the potassium ion has some specific function in determining the potential difference which exists between the inside and outside of a fibre and the action current by which the wave is propagated. Possibly potassium has some specific solubility in the lipoidal substances of the nerve sheath, some specific power of penetrating which other ions have not. The current outward at the cathode by which we suppose excitation to occur is probably carried by potassium ions.

This may explain a phenomenon on which I have not yet touched, that of the gradual adaptation to a slowly increasing current. It has long been known that a current which would normally be strong enough to produce excitation may not do so if its full value be reached not suddenly but slowly. If potassium be the only means of carrying current through the sheath, its continued transfer outwards at the cathode would have the effect of depleting the inside and raising its concentration on the outside, so that a back E.M.F. would be generated (determined by $\frac{RT}{F} \log \frac{C_2}{C_1}$): this might effectively prevent the further transfer of current at a time when the externally applied E.M.F. at last reached the value at which, if suddenly applied, it would excite.

Similarly, we may explain the stimulus occurring at the anode at break of a long-continued constant current. During the prolonged passage of the current the potassium ions on the outside at the anode have been depleted by carriage through the sheath until either so few are available, or the back E.M.F. is so great, that no current can run. Breaking the circuit of the applied E.M.F., the constraint at the anode is released, the unusually high ratio (potassium inside) : (potassium outside) immediately tends to right itself by the back transfer of potassium ions outwards through the membrane. This constitutes a current similar to that which occurs normally at excitation at the cathode; consequently, when the back rush of potassium ions is rapid enough, excitation occurs and an impulse starts off.

The normal function of motor nerves is to transmit impulses to the muscles, and for many years physiologists have discussed how the impulse in the nerve gets across to, and produces its effect in, the muscle fibre. Motor end-plates have been described by histologists, but their functions, and even their existence, are doubtful. It has been supposed that the electric change in the nerve which is an accompaniment of the impulse, starts the process of excitation in the muscle fibres, just as in the laboratory an impulse is started by an electric shock. This idea has led to the view that the muscle fibre and its motor nerve are normally 'isochronous', that is to say, have the same 'excitation time'; a muscle was supposed to respond to the impulse in a nerve if the latter was in tune with it, but not otherwise.

Some years before the War, Keith Lucas showed that in muscle there are two different excitable substances which he supposed were the muscle fibres themselves and the nerve twigs running to them. Lucas's experimental demonstration was denied by Lapicque who, employing different electrodes, found that the excitation time of both tissues was the same. Lucas's observations, however, have been reinstated by Rushton, and it seems doubtful whether Lapicque's claim of normal isochronism between muscle and nerve can stand. The most beautiful application of Lapicque's theory, one which was perhaps just a little too convincing because of its beauty and because it appeared to explain so much, was that of the mechanism by which paralysis is caused by curare or other drugs or by such agencies as fatigue. Normally, the impulse from the nerve passes over into the muscle. A small dose, however, of curare, or the onset of fatigue, somehow breaks the connexion, and Lapicque maintained that this was due to the fact that the curare, or the other paralysing agency, had increased the excitation time of the muscle fibre until it was no longer isochronous with its motor nerve and therefore the impulse from the latter failed to affect it. The case was like that of two tuned electric circuits, sending and receiving—if the receiver were put out of tune with the transmitter, messages were not received.

Various experiments were adduced in support of this theory, and for a time it was accepted and was in danger of becoming a dogma. Unfortunately its experimental basis seems to be at fault. The experiments on which it was founded have been repeated by Rushton and their results denied. Other experiments have been made by which the 'heterochronism' theory of curarisation has been made untenable. It is a strange thing in science to find a theory, so directly based upon apparent experimental facts, displaced by a direct denial of the facts: but so it seems to be.

THE PROPAGATED DISTURBANCE

We have considered the manner in which excitation by an electric current occurs. With every adjustment made to get the most efficient stimulus, the energy in it is still very large when compared with that set free by the nerve itself as an impulse runs along it. Electrical stimulation is very wasteful compared with the natural stimulation from point to point by which an impulse is propagated. This is not difficult to understand. The chief part of the energy of an artificial stimulus is wasted in the fluid between the electrodes outside the active region of the nerve fibres. Only that fraction of the current which, according to our hypothesis, crosses the cathode region of the surface, is effective as a stimulus. In natural stimulation, that is from point to point in the propagation of the wave, there are no electrodes and there can be no short-circuiting in the different fluids: the stimulating current, therefore (if propagation be by means of the current), is far more efficiently used.

There is a tendency to assume, as I have assumed here, that propagation of the impulse from point to point occurs through the agency of the action current which can be detected at an active point. There is no doubt that the action current has the time relations of an efficient stimulus and, properly applied, it should have the magnitude requisite for excitation. We have no picture of the manner in which the excitatory disturbance is propagated, except that which supposes that the action current at any given point 'stimulates' a neighbouring point, where in its turn a further action current is produced, which again stimulates a neighbouring point, and so on. The fact that the velocity of propagation runs parallel with the speed of development of the action current at a given point, and also inversely with the time scale of the process of excitation, strongly suggests that these three factors are linked together in some relation of cause and effect.

It must not be imagined that this self-perpetuating electro-chemical wave is analogous to those waves in physics in which no new energy is required from point to point for the transfer of the wave. In sound, or in light, energy is forced into the medium at the source but no further energy is required for the propagation. Unquestionably in nerve, as the initial heat shows, energy is liberated at each point as the impulse passes by, and, moreover, in the next thirty or forty minutes several times as much energy is set free in restoring completely the *status quo*. With this qualification, however, we can think of the propagated disturbance as some type of self-transmitting electro-chemical wave.

The problem, therefore, of its nature ultimately resolves itself into two : one is that of the change which is produced at the cathode when a current of sufficient intensity causes conditions to become unstable and some mechanism to be fired off ; the other is of the physico-chemical basis of the action current itself. If we could understand these two effects we could make a clearer picture of how the impulse is propagated. It seems likely that as the result of 'excitation' an unstable state is reached, in which the potential difference normally held at the surface of the fibre is for a moment released. It discharges until some change sets in by which the instability is reversed and the initial condition realised once more. Looked at in this way, the action current is nothing more than a momentary discharge of the resting potential, which is normally to be seen between an injured and an uninjured point of a nerve. Our problem, therefore, comes to this, what is the nature of the instability which is produced by a sufficient outward current through the nerve surface, and how is this instability rapidly reversed and the nerve surface restored to its normal state ?

The chemical reactions occurring in muscle are largely those of recovery. Lactic acid formation is involved in the restoration of creatine phosphoric acid which breaks down in activity ; oxidation and the combustion of food-stuffs are involved in the restoration of the lactic acid. In nerve we know that in any case nine-tenths of the energy liberated is involved in recovery. It is not going very much further to suppose that the remaining tenth is involved in the immediate recovery process by which the instability produced by stimulation is reversed. I should picture the primary effect as a physico-chemical one transmitting itself along the surface. The surface is rendered somehow unstable by the passage of a current outwards across it, and the instability is propagated by means of the current it releases. The return of the surface to its normal state is the result of some chemical reaction involving the liberation of free energy. Without this return no further impulse could be propagated.

MITOGENETIC RADIATION IN NERVE

The facts I have described so far are reasonably certain, though their explanation is not. I wish now shortly to refer to some others, of great importance if they are confirmed, but of which the evidence is as yet not quite convincing. During the last few years a number of papers have appeared from Moscow and Leningrad on the subject of so-called 'mitogenetic radiation'. The name implies that the radiation in question is able to cause mitosis in cells, and the approved method of detecting and measuring it is to determine the increase in the number of yeast cells in a suspension subjected to the radiation. Living organisms themselves are said to give out this radiation, particularly when active, and the analysis of the radiation is held to indicate the type of chemical reaction involved in the activity.

The yeast cells prepared in a special manner are held in a suspension which is placed in two tubes, an experimental and a control. The experimental tube is exposed through its open end to the radiation in question, the control is kept without radiation. At the end of the exposure, samples are taken and incubated, and after three or four hours the cells are killed and counted ; the excess of cells in the experimental suspension is expressed as a percentage of the control.

The radiation stated to be given out by living cells is in the ultra-violet region, chiefly between 1900 A. and 2500 A. Its amount is so relatively large that it can be split up by a quartz spectrograph into bands 10 A. wide and each band examined separately for its effect in producing the division of yeast cells.

This is not the occasion to deal with the general question of mitogenetic radiation, but a few months ago a series of papers appeared from the laboratory in Leningrad in which various results obtained from nerve are discussed. If it be true that excited nerve gives out a characteristic radiation which can be used to identify the chemical reactions involved in its activity, then indeed a new day has dawned in the very difficult problem of the physical nature of nerve activity.

In a figure in a recent paper by Kalendaroff (*Pflügers Arch.*, 231), successive spectra, analysed by a quartz spectrograph and the yeast cell indicator, refer to (1) a resting nerve, (2) ground up nerve, (3) mechanical stimulus, radiation from the point of stimulation, (4) electrical stimulus, between the electrodes, (5) injury, radiation 20 mm. from the place of injury, (6) electrical stimulus, radiation 20 mm. away, (7) mechanical stimulus, 20 mm. away. In the lower half of the figure there are spectra for (1) oxidation of pyrogallol in air, (2) glycolysis, (3) action of phosphatase, (4) splitting of creatine-phosphoric acid, (5) splitting off of ammonia from protein.

When we remember that maximal continuous stimulation of nerve does not double its resting metabolism, the variety and strength of the radiation emitted from active nerve, under the comparatively mild stimuli administered to it, are rather astonishing. A vague suspicion that the results are almost too good to be true is a little increased by a subsequent paper by Schamarina which shows an evident misunderstanding of the nature of nerve activity. It is known, and it is an obvious consequence of the existence of a refractory period following the passage of an impulse, that when two nerve impulses start at opposite ends of a nerve and meet in the middle they are unable to pass one another and both are wiped out. When a single impulse traverses the nerve the whole of the nerve goes through a phase of activity. When two impulses start at opposite ends of the nerve they meet in the middle and stop, but again the whole of the nerve has gone through the active phase. If radiation is given out as the result of nerve activity, its emission should occur equally in the two cases. Schamarina, however, expecting that because the two impulses destroy one another, therefore there should be no radiation from the point where they meet, has described experiments in support of the expectation. If the results are true, we need a new picture of the propagated disturbance in nerve.

The suspicion is strengthened by a further paper by Brainess describing the use of the same technique for the study of human fatigue. At the beginning of this remarkable paper it is stated that modern methods for investigating the phenomena of fatigue in man leave much to be desired, and that the author therefore took up the method of mitogenetic radiation in order to find a new and more accurate means of describing the state of fatigue in a factory worker. One hundred girls working in an electrical factory were examined, samples of their blood being taken at eight in the morning, at three in the afternoon and at five in the afternoon. The blood was dried on filter paper, then dissolved in distilled water and finally allowed to give out its radiation, which was measured as usual by the yeast cells. At eight in the morning the mean value of the radiation coming from their blood was 28, as measured by the percentage increase, over the control, of the number of cells in the yeast suspension. After seven hours work the girls were apparently completely exhausted, for their blood gave out no radiation at all, except in a few isolated cases. After two hours rest the radiation had risen to 28 again.

Of the social and industrial importance of these results, supposing them to be true, I need not speak, though I wonder if there are many British factory operatives who would be found completely exhausted, even of 'radiation', after seven hours work. An even stranger result follows. Not only did hæmolysed blood emit radiation which was abolished by seven hours work in a factory, but also the cornea and the conjunctiva did the same. The girls apparently had only to look at the yeast cells to set them dividing! At eight in the morning the radiation from the girls' eyes had a mean value of 24, after seven hours work it had a mean value of 4, after two hours recovery a mean value of 20. Finally—and most unromantically—it is stated that the spectrum analysis of the radiation given out by the girls' eyes showed that its only important component is that due to glycolysis!

It is not easy, in the case of the paper describing the results of the two nerve impulses meeting one another, to avoid the feeling that the expectation of a certain result has had something to do with its appearance, and it is difficult not to draw the same conclusion from the paper describing the new test for fatigue. The claims made are clearly most important if they can be verified, and one hopes that verification may soon be at hand. The difficulty in understanding nerve is largely that the changes in it are too small for ordinary chemical methods to detect. If the new methods elaborated by our Russian colleagues can throw real light on the subject, then we shall be deeply indeed in their debt. At present, however, one cannot stifle suspicion that the phenomena described may have more to do with the enthusiasm of those who describe them than with the physical nature of the nerve itself.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

A grant has been received also from the International Cancer Research Foundation, an organisation established last year in Philadelphia by Mr. William H. Donner and endowed by him with a sum of 2,000,000 dollars. Although its administrative headquarters are situated in America, the Foundation is world-wide in its scope. The income of the fund is to be applied to assist research into the causes, prevention, control, relief and cure of cancer, and this income is to be so distributed that not less than 35 per cent nor more than 50 per cent is to be allotted in countries other than the United States. The trustees have awarded a sum of £1,000 a year for a period of two years to the Cancer Hospital Research Institute in support of investigations into factors which underlie the origin of malignant growths. This sum will provide two research studentships, to one of which Mr. G. A. D. Haslewood has been appointed. The two research students will undertake the investigations of special problems in connexion with the general scheme of research now in progress at the Cancer Hospital.

Protection against Lightning

WE welcome the handbook entitled "Code for Protection against Lightning", a revised edition of which has just been published (U.S. Government Printing Office, Washington, 1933, 15 cents). The number of fatalities from lightning in the United States is insignificant in comparison with the 100,000 annually from all other accidental causes. But the suddenness with which the flash happens, and the apparent impossibility of telling where it may strike next, may well frighten the bravest. Directions are therefore given for personal conduct during thunderstorms. If it is necessary to be out of doors, it is desirable to keep away from small sheds in exposed localities, isolated trees, wire fences, hilltops and wide open spaces. Shelter can be sought in a cave, a depression in the ground, a deep valley, at the foot of a steep or overhung cliff or in a grove of trees. Best of all is to stay indoors and keep away from fireplaces, stoves and all other large metal objects. Modern buildings are safe because of the protective effects of the metal used in constructing them and the metal piping on the exterior walls. The rules for erecting lightning conductors are now practically standardised. An approved protector should be placed as near as practicable to the point of entrance of an aerial telephone wire into a building. Metal radio masts should be bonded to the nearest lightning conductor. Wooden radio masts which extend six feet or so above the highest parts of the building should be provided with a connexion to earth. In an appendix, various kinds of lightning phenomena are described and modern theories are explained. A very instructive map is given showing the average number of days on which thunderstorms occur at many stations in the United States and Canada. There are very few thunderstorms on the Pacific Coast but at Tampa in Florida the number of days per annum on which thunderstorms occur is 94.

Archæological Exploration in Oaxaca, Mexico

RECENT reports received by Science Service, Washington, D.C., from Miss Emma Reh, who is engaged in archæological exploration in Mexico, point to the possibility of further discoveries bearing on the problem of the position of Mixtec culture and the area now known as the province of Oaxaca as a connecting link between the Mayan culture to the south and Mexican culture to the north. It will be remembered that this was the problem on which S. Alfonso Caso was engaged at the time he discovered the treasure tomb of Monte Alban a year ago. Miss Reh has recently examined the sites of two ruined cities in the mountainous Mixteca area, Teposcolula and Hualmelulpan, situated eighteen miles apart, neither of which had previously been recorded on the official archæological map of Mexico. Hualmelulpan was an important centre which once dominated the road from north to south. In the inner of two pyramids, built one over the other, Indians have found a number of sculptures and idols. Among them Miss Reh reports a sculptured slab which bears the date "Thirteen Stone Knife" in the Mayan numeral system, constituting an important link with the Mayan culture to the south. Among other material is a human figure more than six feet high carved from stone, which shows a snarling mouth armed with formidable fangs. This may be the ancient Mixtec deity Tepeyolotl, "Heart of the Mountains", often represented as a tiger. Pottery heads found on the mounds and terraces range in series extending from 'Mixtecan' to 'archaic'.

Accommodation for Paying Patients at Voluntary Hospitals

THERE is a growing demand for nursing accommodation for those who, unable to pay the charges of a nursing home, desire better accommodation or more privacy than is provided in ordinary hospital wards and are willing to pay for it. King Edward's Hospital Fund for London has therefore issued a list of the 'pay beds' at hospitals making returns to the King's Fund, with particulars of the accommodation and of the normal weekly charge. The pamphlet may be obtained from the Fund, 7 Walbrook, E.C.4, price 3*d.* including postage.

Health of the British Army during 1931

IN the report on the health of the army for the year 1931 (H.M. Stationery Office. 2*s.* 6*d.* net), the Director-General, Lieut.-Gen. Fawcus, states that the health of all ranks both at home and abroad was satisfactory. With an average strength of 181,508, the principal causes of admission to hospital were influenza, malaria, and venereal diseases, with 8,324, 7,191, and 5,865 cases respectively. Tonsilitis accounts for 5,752 cases, a decrease over the previous year. Dysentery has increased somewhat. Venereal diseases have shown an almost steady fall during the last ten years, from 70 per 1,000 strength in 1922 to 33 per 1,000 in 1931.

Californian Earthquake of March 10

LATER accounts of this earthquake show that, though stronger than the Santa Barbara earthquake of 1925, it is not to be numbered among the great earthquakes of California. The epicentre is placed by the U.S. Coast and Geodetic Survey in lat. 33·7° N., long. 118·9° W., a point in the San Pedro channel, about twenty-five miles west of San Pedro Point (Science Service, Washington, D.C., March 11). The earthquake was thus probably due to a movement along the submarine San Pedro fault zone. The earthquake of July 28, 1769, also seems to have been felt most severely along the shore of San Pedro Bay and may therefore have been connected with the same fault zone.

Plastic Materials

ALTHOUGH a large number of new industries dealing with the products of plastic materials have been established in recent years, it is not yet realised the extent to which these 'substitute' materials have nowadays replaced natural products. In order to introduce plastic materials to other industries, as well as to the public, an exhibition was opened by Lord Irwin at the Science Museum, South Kensington, on April 5, which traces the course of the plastics industry from the various raw materials used in the production of plastics to the final product of artificial wood, china, horn and metals. Natural and synthetic resins, cellulose and casein are the principal bases on which the new industries depend and from these has been built up a wide variety of manufactures, ranging from aircraft accessories, buttons, dental instruments, electric insulation, fancy goods, furniture, gramophone records, combs, spectacle cases to scientific instruments and such sports requisites as golf balls and billiard balls. The term 'plastic materials' covers a number of natural and artificial chemical products, the chief property of which is that they can take shape or form under pressure. One of the most interesting features of the exhibition is a room in which the furniture and the surfaces are made entirely of plastic materials. The exhibition will remain open until the end of September.

Announcements

WING-COMDR. THE HON. MAURICE BARING, Prof. W. Langdon Brown, Regius professor of physic in the University of Cambridge, and Prof. H. H. Dodwell, professor of history of the British Dominions in Asia, School of Oriental Studies, have been elected members of the Athenæum Club under the provisions of Rule II of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service.

PROF. H. E. ARMSTRONG will deliver the Huxley Memorial Lecture at the Imperial College of Science and Technology, South Kensington, on Thursday, May 4, at 5.30 p.m. His subject will be "Our Need to Honour Huxley's Will".

A DAVID ANDERSON-BERRY gold medal, together with a sum of money amounting to about £100, will be awarded in July 1935 by the Royal Society of Edinburgh to the person who, in the opinion of the Council, has recently produced the best work on the nature of X-rays in their therapeutical effect on human diseases. A similar award will be made every three years.

M. ALBERT PORTEVIN, president of the Société des Ingénieurs Civils de France, will deliver the twenty-third annual May lecture before the Institute of Metals at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, on May 10, at 8 p.m. The subject of the lecture will be "Quenching and Tempering Phenomena in Alloys".

SILVER medals of the Royal Aeronautical Society have been awarded to Mr. D. L. H. Williams for his work in designing the Fairey long-range monoplane in which Squadron Leader Gayford and Flight Lieutenant Nicholetts made a record non-stop flight to South Africa, and to Mr. A. H. R. Fedden for his work on air-cooled engines, particularly the Bristol Pegasus engine used in the biplane in which Mr. C. F. Uwins recently attained a height of 43,976 ft.

AT the annual general meeting of the Physical Society held on March 17 the following officers were elected: —*President*, Prof. A. O. Rankine; *Vice-President*, Prof. W. Wilson; *Secretaries*, Dr. Allan Ferguson (Papers), Dr. Ezer Griffiths (Business); *Foreign Secretary*, Prof. O. W. Richardson; *Treasurer*, Mr. R. S. Whipple; *Librarian*, Dr. J. H. Brinkworth; *New Members of Council*, Prof. E. V. Appleton, Dr. L. F. Bates, Dr. L. Hartshorn.

AT the annual corporate meeting of the Institution of Chemical Engineers, held on February 17, the following officers were elected: *President*, The Right Hon. the Viscount Leverhulme; *Vice-Presidents*, Dr. H. Levinstein, Mr. H. Talbot; *Hon. Secretary*, Mr. H. W. Cremer; *Hon. Treasurer*, Mr. F. A. Greene; *Members of Council*, Col. E. Briggs, Mr. H. J. Pooley, Dr. F. S. Sinnatt; *Associate-Members*, Mr. C. C. H. Brazier, Mr. H. A. S. Gothard. The Osborne Reynolds medal for the year 1932 was presented to Mr. S. G. M. Ure, in recognition of his valuable services to the Institution as honorary editor of the *Transactions* for the past seven years. The Moulton medal for the best paper read before the Institution during the year was awarded to Dr. C. M. White, for a paper entitled "Fluid Friction and its Relation to Heat Transfer", and the Junior Moulton medal and prize of books was awarded to Dr. W. B. Hawes for a paper entitled "Some Side-lights on the Heat Transfer Problem".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A staff lecturer at the Northern Counties Training College of Domestic Science, Northumberland Road, Newcastle-upon-Tyne—The Principal (April 10). A head of the mechanical engineering department of Rutherford Technical College—The Director of Education, Education Office, Northumberland Road, Newcastle-upon-Tyne (April 22).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Spectrum and Latitude Variation of Penetrating Radiation

I HAVE made some calculations on the spectrum and latitude variation of penetrating radiation on the assumption that it consists of electrons coming to the earth from outside.

If we assume that the electrons are incident on the atmosphere uniformly in all directions, it may be shown that the number of incident electrons with a range R, is proportional to the value of xd^2I/dx^2 at a depth $x = R$. I denotes the intensity of ionisation at a depth x, the latter and the range R being measured in terms of distances travelled in a homogeneous medium. The derivation of this relation, and the exact conditions of its applicability, will be given elsewhere. By means of it, and also the relation between range and energy, we can deduce the energy spectrum of the incident electrons directly from the ionisation-depth variation.

The distribution of the electrons responsible for the ionisation at any given depth may be obtained from the distribution of the incident electrons by allowing for the absorption by the superincumbent matter. The curve in Fig. 1 represents the results obtained in this way for the incident energy spectrum (averaged over all directions) of the electrons responsible for the ionisation at sea level (76 cm. pressure).

These results depend upon the assumption that the electrons are incident on the atmosphere isotropically. The fact that the ionisation due to penetrating radiation is independent of the time, proves that the distribution of the electrons in outer space is isotropic. This is not necessarily the case at the surface of the earth, on account of the effect of the earth's magnetic field. The latter effect has been recently investigated in detail by Lemaître and Vallarta[1]. They find that for electrons of a given energy there exists a latitude, λ, above which the distribution of the electrons at the earth's surface is not at all affected by the earth's magnetic field, and is therefore isotropic. The value, λ_m, of λ, corresponding to the minimum energy, T_m, which an electron must have in order to reach sea level, is about 50°. The ionisation-depth data used here were obtained in experiments made in higher latitudes than this. It follows that the results represented by the curve in Fig. 1 are not invalidated by the assumption of isotropic incidence.

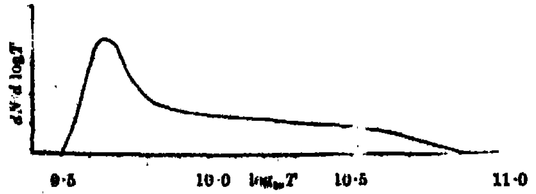

FIG. 1.—Distribution of incident energies of electrons responsible for sea level ionisation. T = energy in volts.

For latitudes $<\lambda_m$, electrons with $T > T_m$, that is, electrons with sufficient energy to reach sea-level in certain directions, are not all incident isotropically. Certain directions of incidence for certain energies are disallowed. The sea level ionisation in these cases is obtained by considering the absorbing effect of the atmosphere on the electrons incident in the allowed directions. Using the numerical results for these allowed directions given by Lemaître and Vallarta, we obtain in this way curve A, (Fig. 2), for the variation of sea level ionisation with magnetic latitude*.

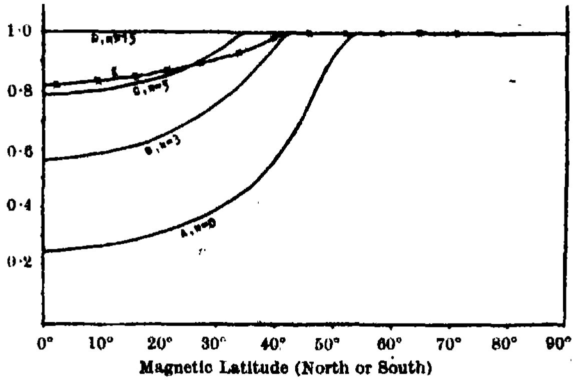

FIG. 2.—Variation of sea level ionisation with latitude. Value at poles taken as unity for calculated curves. Value at highest latitude investigated taken as unity for experimental curve.

The requirements that the falling off in the ionisation, as the equator is approached, should start suddenly at a certain latitude, and also be symmetrical about the equator, satisfies the outstanding features of the experimental results. The latter are represented in Fig. 2 by curve E (marked with crosses). This agreement makes it almost certain that at least part of penetrating radiation is due to the existence of an isotropic distribution of high-energy electrons in outer space. The existence of a fairly critical latitude arises from the calculations by virtue of, (*a*) the above result obtained by Lemaître and Vallarta that for electrons of a given energy there is no effect on their distribution at the surface of the earth above a certain latitude, (*b*) the result that the energy spectrum of the electrons concerned starts suddenly at a certain energy.

The quantitative discrepancy between curves A and E indicates either an admixture of photons, or a greater rate of dissipation of energy by the electrons than is attributed to them in the calculations. In the calculations leading to A, it is assumed that the penetrating electrons interact only with the extra-nuclear electrons of the matter traversed, and that this interaction obeys quantum mechanics. There is, however, definite experimental evidence for nuclear interaction. Assuming that the latter gives rise to a stopping-power n times the theoretical value due to extra-nuclear interaction, we obtain curve B for $n = 3$, and curve C for $n = 5$. If the nuclear effect consists in the ejection from the nucleus of high-energy electrons and protons, which acquire their energy from the primary electron, then n roughly represents the average number of particles in equilibrium with one primary electron. The frequent occurrence of groups of two or more associated tracks within the relatively small dimensions of a Wilson cloud chamber, indicates that $n \sim 5$ is not improbable.

The correction to the spectrum in Fig. 1 due to the above nuclear effect consists in a lateral displacement of the curve by $+\log_{10}n$. As regards the spectrum of all the ionising particles at sea level, which have energies greater than 10^7 volts, a value of $n=5$ requires about 10 per cent of them to have energies greater than 10^{10} volts, and 2 per cent to have energies greater than 10^{11} volts. These estimates assume that the secondary particles have energies between 10^7 and 10^{10} volts.

---

* Certain approximations were made in the calculations. The resulting possible errors in the calculated curves, and also the extent to which curve *E* is not an exact representation of the experimental results, are not of a magnitude which affects the present discussion.

Absorption Spectrum of the Vitamin E Fraction of Wheat-Germ Oil

So far as we are aware, the only attempt to investigate the absorption spectrum of vitamin E hitherto published is that of Evans and Burr[1], who reported that the vitamin E fraction of wheat-germ oil, while having high general absorption, did not give any definite bands that might help in following the concentration of the vitamin. We have now re-examined this point and have obtained results of a more promising character.

The absorption bands given by the untreated wheat-germ oil were so numerous and diffuse that it was difficult to disentangle them. At the temperature of liquid air, however, the broad diffuse bands became sharper and many of them showed detailed structure, so that the task of analysing and allotting them was rendered very much easier. A description of the bands shown by the non-vitamin fractions will be given elsewhere. The vitamin E fraction, obtained by the saponification of the oil by alcoholic potash at 37° C., followed by extraction with ether and the removal of sterols from the non-saponifiable residue by crystallisation and precipitation by digitonin, gave the curve shown in Fig. 1. The height of the peaks is given only approximately from photometered plates.

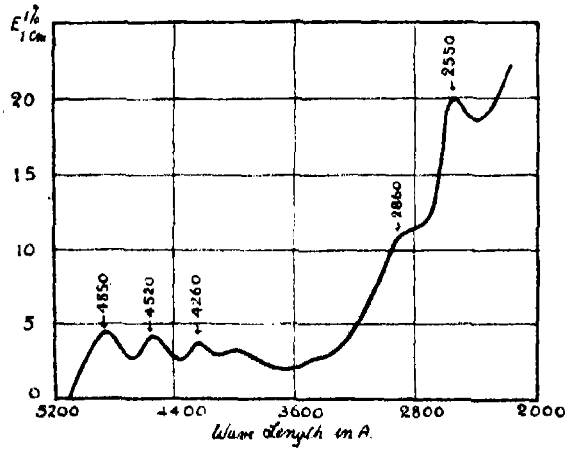

FIG. 1.

The spectrum includes three well-defined bands in the blue with maxima at 4850, 4520 and 4260 A. These bands, which were remarkably sharp even at ordinary temperatures, were detected in the original oil, but their strength was increased fifty-fold in the concentrate. In the ultra-violet (apart from a small band at 3370 A.) stronger absorption began at 3020 A. with a small step-out at 2860 A. and a well defined maximum at 2550 A., followed by general absorption from 2400 A. down.

The absorption bands were not affected by prolonged exposure of the concentrate to air or oxygen at room temperature, while the only effect of hydrogen peroxide was to increase slightly the absorption in the far ultra-violet at 2400 A. A stream of 10 per cent ozone, however, passed for a few seconds destroyed both the visible bands and the incipient absorption in the ultra-violet at 3020 A. and 2860 A. The band at 2550 A. was more resistant and was little changed. More prolonged ozonisation caused heavy continuous absorption in the ultra-violet.

The concentrate was not sensitive to light of wavelengths longer than 4000 A., but exposure to the full light of a mercury arc for a period of 45 minutes destroyed the bands in the visible spectrum as well as the incipient absorption at 3020 A. and 2860 A. The band at 2550 A. was, however, again but little changed.

Experiments on the selective destruction of the various bands by monochromatic irradiation, on the correlation of the strength of bands with biological activity, and on the absorption bands of concentrates of vitamin E from various sources are now in progress.

Polarisation of Echoes from the Kennelly-Heaviside Layer

THE object of this letter is to correct an error made by me in a letter published in NATURE of September 10, 1932, p. 398. The letter dealt with the subject of the polarisation of echoes reflected from the Kennelly-Heaviside layer. It was stated that according to the magneto ionic theory the left-hand circularly polarised ray should be more attenuated than the right-hand one. This is an error and the reverse is the case. I have to thank Prof. Appleton and Mr. Radcliffe for pointing this out in their letter to NATURE of September 24, 1932, p. 472.

An accidental reversal of a ± sign on turning over a page was the cause of the trouble. There is now no disagreement on the theoretical side. As regards the experimental results I find, on looking up my records, that at any rate in one case, the polarisation of the single surviving F_1 echo after the split echo had disappeared was measured in the period immediately following the determination of the polarisation of the components of the split echo, so that the polarisation of the survivor was without doubt the same as the polarisation of the most bent ray in the split doublet, that is, right-handed. This condition persisted, on this occasion, for most of the afternoon.

Recent experience with an improved receiver has substantially confirmed our original observations as to the opposite polarisations of split rays, but indicates that it is impossible to generalise with regard to the strength of the various types of rays.

We have had periods on which the F_1 ray is predominantly right-handed and periods when F_1 is the opposite, and again periods when F_1 alternates between right-hand and left-hand with periods of plane polarisation in between. So far as a rather limited set of observations goes, during the daytime F_1' and F_1'', the right- and left-hand circularly polarised echoes respectively, appear on the average to be of the same order of strength. F_2 and F_3 are, however, predominantly left-handed although right-handed F_2 and F_3 have occasionally been observed. The wave-length used throughout these experiments was 60 m. and the base line between transmitter and receiver was 1·2 km.

It may be of interest to note that we have been able to get echoes from a neighbouring transmitter about 50 yards from the receiver which only radiated between 0·1 and 1 watt; the received intensities varied between a fraction of a microvolt/m. and about 20 μv./m.

Acceleration of the Decomposition of Crystals of Barium Azide by the Emission from Radium Emanation

DEHYDRATED crystals of barium azide decompose at a measurable rate above 100° C. giving nitrogen as a gaseous product. There is an induction period very similar to that observed with mercury fulminate and the reaction spreads from centres of metallic barium formed on the surface and in the interior of the crystal (F. E. Harvey, unpublished). The induction period is shortened and the rate of centre formation increased if the crystals are exposed to the emission from a platinum seed containing radium emanation. At 110° C., the induction period is shortened from 120 min. to 55 min. and the rate of acceleration of the reaction trebled when the intensity of the emission from the emanation seed is about 1 m. curie.

The experiments so far carried out indicate that the acceleration of the reaction is due to an increased rate of nuclear formation. From the nuclei of metallic barium formed, the reaction spreads out at a rate which is about three times greater than for nuclei formed by thermal means.

Crystal Structure of Diphenyl Series

A COMPARISON of the results of crystal structure analyses of diphenyl, *p*-diphenylbenzene and *p*-diphenyldiphenyl gives evidence that in this series of compounds the benzene rings in each molecule are coplanar and linearly extended. The three substances crystallise in structures of $P\,2_1/a$ symmetry with unit cells which are nearly identical in the *a* and *b* directions and have the respective lengths of 9·50, 13·59 and 17·72 A. along the *c* axis. From the marked similarity not only in dimensions but also in the intensity of those reflections which are less dependent on the length of the molecule, it is apparent that there is a similarity of structure and that in each case the length of the molecule is roughly parallel to the *c* axis.

The orientation of the benzene rings in the diphenyl crystal was determined by Krishnan from magnetic susceptibility measurements and confirmed by Dhar in an X-ray study. The molecule was found to be planar and its position in the unit cell was defined. The structure of *p*-diphenylbenzene has now been determined in this Laboratory and a Fourier analysis will shortly be published. The results show that the molecule is extended in a single plane at a tilt to the axes which, though not identical with that in the above case, does involve a similar alignment of the molecules with respect to each other. Preliminary results from the study of *p*-diphenyldiphenyl indicate that a corresponding arrangement exists in this case. I should very much like to hear of higher compounds of this series which would be available for study.

A comparison of the optical properties of these compounds is of interest. In all three substances the optic axes lie in the 010 plane and one optic axis is in the field when viewed along the perpendicular to the 001 face. In each case the ray vibrating in the direction most nearly parallel to the length of the molecule is the slow ray. The three compounds are optically positive and the degree of curvature of the isogyre shows that they become increasingly positive as the molecule lengthens. This is to be expected, since, with an increasing number of phenyl groups, the chain character of the molecule becomes relatively more important than its planar character, especially as the molecules are parallel as regards their length but have their planes mutually inclined at an angle of approximately 66°. It is proposed to carry on a more detailed study of the optical and magnetic properties of the series in this Laboratory.

LUCY W. PICKETT.

Strange Spatfall of the Common Mussel on the Common Cockle

AN interesting and unusual spatfall of the common mussel, *Mytilus edulis*, on the common cockle, *Cardium edule*, resulting in a related and dual mortality was observed in 1932 in the course of investigations on the extensive cockle beds of Cark sands at the head of Morecambe Bay. In June, heavy falls of mussel spat (5–10 mm. long) were found in several large areas on these beds, an event unprecedented in the experience of local middle-aged fishermen. At low water on these desert-like sands, the areas with mussels loomed in the distance like rocky outcrops. Such an unusual spatfall may be regarded as a natural experiment on the part of *Mytilus* to establish itself on sandy ground.

The spat had settled about and below half-tide mark actually on living cockles, which were so abundant in parts as to push one another to the surface of the sand. The fishermen were commonly taking 1 cwt. of cockles (mean length about 30 mm.) from about 10 square yards of ground at the lower levels (about 45 individuals per square foot). An important bionomic feature of these grounds is that, wherever examined, the sand was found to contain but little silt and to pass wholly through a sieve with 0·5 mm. circular holes. In November one of these areas was again visited and examined. It was found to be littered predominantly with clumps of dead cockles lying on the surface of the sand and held together by the byssus threads of recently existing mussels. A few living and moribund cockles could be found here and there among the clumps. Gaping mussel shells ranging to about 31 mm. in length remained attached in many of the clumps, while groups of ten to thirty small, living mussels (to 23 mm.) could also be found occasionally among the collections of dead cockles. It would seem that the original clumps had been worked out of the ground by wave-action and that the cockles held fast by the byssus threads had been unable to burrow again.

In view of the doubtful compatibility of sand and mussels[1] this natural experiment is of much interest. The results at the end of the summer show clearly that most of the affected *Cardium* died, and that the loss of *Mytilus* was so great as to render the spatfall a failure.

The population of *Cardium* existing on the beds consisted mainly of individuals of medium size (and age), for the frosts in the early months of 1929 destroyed such large numbers—according to local fishermen—that economic collecting became difficult in 1930. The total yield of cockles from the Lancashire and Western Sea-Fisheries District in the years 1928–32 was 20,746, 10,892, 9,195, 14,846, and 17,117 cwt. respectively, while those for the important last quarter in the year were respectively 5,816, 1,969, 5,413, 6,607, 7,601 cwt.[2] At Cark it is noteworthy that the recovery in 1932—three years after the destructive frosts—was so complete that *Cardium* was considered to be unusually abundant. These facts are of interest in connexion with other observed effects of the unusually cold weather of 1929[3].

The cockles in the clumps would appear to have died from various subjective causes, and senility may be regarded as non-significant. As very little force is apparently required to prevent the valves of lamellibranch shells opening[4] (unsuspected factors may however add somewhat to the known force) it is probable that the entangling byssus threads of the mussels frequently effected more or less permanent occlusion of the shell-valves of *Cardium*, thus tending to starvation and difficulties in respiration. The unusual exposure of *Cardium* on the surface of the sand would subject the animals to wide and unusual variations in temperature, and might very well also involve difficulties in the operation of the feeding mechanism[5,6]—even in unimpeded feeding—over a labile substratum of loose fine sand.

The failure of the mussel spatfall was no doubt partly due to the attacks of predatory fishes, but since numerous empty valves occurred in the clumps, subjective death had occurred and probably from the same causes as operated on *Cardium*. Owing to the strong tidal currents over the beds, it is probable that the water surrounding the clumps would be rarely free from suspended sandy particles, and *Mytilus* may be expected to be less well adapted for dealing with such a situation than is *Cardium*, which possesses an internal *gill-shield* against which the ingoing current would tend to impinge[5].

From the facts of this natural experiment it may be concluded that (*a*) mussel spat was present in the spring in the water over a large area of the beds in a condition to settle on suitable places; (*b*) settlement was not effected on sand; (*c*) settlement was effected on cockles in certain places where these were abundant; (*d*) the latter spatfall was a virtual failure and resulted in killing the animals used for attachment. It is a reasonable deduction from the facts that mussel spat cannot effect a settlement on fine sand consisting of particles less than 0·5 mm. in diameter, but that given a larger firm surface a temporary lodgment may be attained.

Control of Respiratory Movements in Crustacea

WHEREAS in mammals the factors controlling lung ventilation have been intensively studied, data for respiratory control in the invertebrates are relatively scarce. The cases hitherto investigated of the environmental factors (other than temperature) which influence respiratory movements in the invertebrates have shown that sometimes both carbon dioxide excess *and oxygen deficiency act as stimulants* (snails[1], *Octopus*[2], insects[3,4]), sometimes carbon dioxide alone is effective (*Squilla*[5]), while in other cases it is oxygen alone which is responsible (*Tubifex*[6]).

We have undertaken a comparative study of the controlling factors in members of a single group of invertebrates, the Crustacea, which live in a variety of different habitats. The results are briefly as follows. Neither carbon dioxide excess nor oxygen deficiency in the water accelerates the rate of respiratory movements in the barnacle *Balanus balanoides* (opercular valves) or in *Cheirocephalus diaphanus* (limbs). Oxygen deficiency, but not carbon dioxide excess, accelerates the scaphognathite beat of the crayfish *Astacus fluviatilis* and the pleopod movements of the fresh-water isopod *Asellus aquaticus*. Both an increase in the amount of dissolved carbon dioxide in the environment and a decrease in its oxygen content quicken the pleopod beat in the amphipods *Gammarus pulex* and *G. locusta*.

It is thus clear that not only in the invertebrates generally, but even within one group, the Crustacea, there is great diversity in the response of the respiratory appendages to oxygen lack and carbon dioxide accumulation. It is not known what is the ecological significance of such differences, nor do we yet understand their physiological causes. Are respiratory centres excited by blood stimuli or by nerve impulses from chemical receptors? The small size of most invertebrates has not permitted the question of blood stimuli to be studied directly; there is evidence, on the other hand, that at least in some forms chemical receptors are operative (*Tubifex*[6], cockroach[4]).

In the amphipods which we have studied it is unlikely that a nervous reflex is involved since there is a considerable latent period before the response appears. With these animals the effects of both oxygen deficiency and carbon dioxide excess are so closely similar that a common cause is suggested, which may be a fall in blood *p*H caused in the case of oxygen lack by incomplete oxidation of acid metabolites. It is clear, however, that oxygen deficiency cannot thus act through blood *p*H in all animals, for we found that while oxygen lack accelerates the respiratory rhythm in the crayfish and in isopods, carbon dioxide excess does not do so, Respiratory control is more efficient in the fresh-water amphipod *Gammarus pulex* than in the marine species *G. locusta*, for in the former the accelerated pleopod beat is permanent at each increased carbon dioxide or diminished oxygen tension, while in the latter it is transitory. This greater efficiency may be necessary to *G. pulex* because its oxygen consumption is twice that of *G. locusta*[7].

'Raw' Weather

IN NATURE of January 7, the question is raised why moist cold air should feel 'raw'. Sir Leonard Hill, in the same issue, gives an explanation very commonly accepted in physiological circles. May I direct attention to some comments on this topic made by me in the *Journal of Physiology*, vol. 57, 1923? "The uncomfortable feeling caused by cold moist air is attributed, so far as any explanation has been given, to the moist air being a better conductor of heat than dry air. This cannot, however, be the correct explanation, for the diathermic properties of all ordinary gases and mixtures of gases are very close to each other. The cause I take to be that in moist air there is a partial equilibration of the skin gel with the vapour pressure of water in the air leading to a swelling and to a diminution of the small air spaces. The swelling is, in fact, detectable with a strong lens or with a low power of the microscope. As a result of this diminished air enclosed between the epidermic scales the conducting power of the skin is increased".

Time Determination

I SUGGESTED a new method of observation for time determination in my letter in NATURE for October 29, 1932[1], and Mr. H. L. P. Jolly has made some interesting comments thereon[2]. My principal aim was to find a method which would be sensibly free from systematic error. Since my first communication, observations have been obtained in India with a first experimental equipment by three observers—Messrs. Mathur, Banerji and myself on seven nights each, before I came away from India on leave; and further observations on fourteen evenings have since been made by Mathur and Banerji.

With ten stars observed, the range of variation on any one evening never exceeded 0·3 sec. For precision the equipment needs to be improved before it can compete with the moving wire micrometer method, with which at Greenwich the variation between five time stars rarely reaches 0·1 sec. But as regards personality, I think the results are encouraging. They are

$$\text{M.} - \text{B.} = 0{\cdot}012 \pm 0{\cdot}010 \text{ sec.}$$
$$\text{H.} - \tfrac{1}{2}(\text{M.} + \text{B.}) = 0{\cdot}002 \pm 0{\cdot}012 \text{ sec.}$$

Personality appears to be quite as small as that found with the moving wire micrometer. Perhaps it is definitely smaller—but the observations are not yet sufficiently extensive to decide this. The method, then, promises well as regards observer's personality.

As regards systematic error due to mechanical causes, Mr. Jolly has pointed out advantages of this method owing to the reduction of mechanism, which he would like to eliminate entirely. As matters stand, the shutter is very small and its motion is minute. Its very motion may be incorporated in the wireless time signal receiving circuits and so compared directly with the rhythmic signals by the coincidence method. The shutter motion may be regarded as the clock indication of time; then only *variations* of lag of the shutter motion, occurring during star observations and time signal reception, are significant. I fancy that there should be little difficulty in keeping this variation down to a few thousandths of a second.

For geodetic purposes of determination of field longitudes, present-day requirements will be met amply if a probable error of 0·01 sec. is not exceeded, so long as systematic error also is no greater. For fixed observatories studying variation of longitude, these limits should be reduced tenfold, if results are to be on a footing with those of observations for variation of latitude.

The Borrowed Days

IN the Calendar of Nature Topics in NATURE of March 25, page 445, there is a note about this legend. No reference is made, however, to the change from the Julian calendar to the Gregorian, whereof the effect at the present time has been to cause April 10–13 new style to correspond with March 29–31 old style.

The legend itself was no doubt in full currency long before the change of calendar; witness the following passage in "The Complaynt of Scotland", published in 1549.

"There eftir i entrit in ane grene forest, to contempill the tender yong frutes of grene treis, becaus the borial blastis of the thre borowing dais of Marche had chaissit fragrant flureise of evyrie fruit tree far athwart the fieldis."

Among Scottish country folk the legend still runs in rhyme, thus:

"March says to Averil,
'I see three hoggs on yonder hill.
If ye will lend me days three,
I'll find the way to mak them dee.'
The first day it was wind and weet;
The second day was snaw and sleet;
The third day it was sic a freeze
It frose the birds' nebs to the trees.
When thae three days was past and gane,
The silly hoggs came hirpling hame."

Hoggs in Scots are not swine, but two-year-old sheep.

Whauphill,
Wigtownshire.

Research Items

Chastity in Bechuanaland. Changes in the attitude of the Southern Bantu to premarital chastity and pregnancy and their cause are discussed by Dr. I. Shapera in *Africa*, vol. 6, No. 1, in the light of investigations among the BaKxatla of the Sotho-Tšwana cluster in Bechuanaland Protectorate. As among other tribes of the group, the essential element in marriage is the transfer of cattle from the family of the bridegroom to that of the bride, known under the name of *boxadi*. According to traditional practice, strict chastity used to be required of both sexes before they entered the initiation classes, and any boy who was known to have transgressed was liable to be killed while under instruction and in any event was regarded as having disgraced his family and tribe; while a girl who became pregnant had to submit to a variety of humiliations, as well as mockery from other girls, this last being the most serious deterrent of all. The child was either aborted or killed at birth. On completion of initiation, the girl was usually married at once, while the boys were drafted into regiments, and as they were permitted to marry only girls from an age-class junior to their own, marriage was postponed for some years, during which period they had access to the younger wives of other members of their family—usually of the father's younger brother. The changed attitude of the present day, characterised by looseness of morals and a much milder attitude towards the unmarried mother, is due to a variety of causes, among which are mentioned the abolition of the initiation classes at the instance of the Church, freer intercourse between the sexes before and after adolescence, the greater license of the youths awaiting admission to the regiments, the freedom in sexual matters acquired by the men while away in European employment and the preponderance in the number of women owing to the fact that many males do not return to the tribe when they once leave.

Census of Nigeria. The reports and detailed figures of the 1931 census of Nigeria have now been published in six volumes ("Census of Nigeria 1931." 1932–33. London: Crown Agents for the Colonies.) In spite of severe curtailments in field work on the score of economy, the census reveals much of interest in problems of race distribution and changes in Nigeria. In vol. 1 the results as a whole are discussed by Mr. S. M. Jacob. In the Northern Provinces, intensive counts were made in many villages throughout the area. For the rest, the figures were obtained by compilation from village lists, but on the whole are considered to have an error of not more than five per cent, and so low as one per cent in the intensive data. In the Southern Provinces, outside Lagos, there was no actual count and the figures are based on a computation derived from the number of taxable males. The margin of error is thought to be ten to twenty per cent. In Lagos, where a count was made, the error may be so high as ten per cent. The total figures for Nigeria, 19,928,000, show a seven per cent increase on those for 1921 but the 1921 figures cannot be regarded as accurate. Certain tribes appear to be increasing in number, Kanuri, Fulani, and Tuareg in the north, and Yoruba in the south, but Nupe in the north and several of the forest tribes of the Cameroons are infertile and tending to disappear. An extensive census of the southern provinces seems to be a desirable measure. A noteworthy feature is the remarkable drop in the death rate of Lagos for both native and European.

Census of Wapiti Deer in Wyoming. A co-operative count of wapiti, universally known as 'elk' in North America, was shared during the winter of 1931–32 by the U.S. Biological Survey, the Forest Service, and the Wyoming State Game Commission. Ground work was supplemented by use of an aeroplane, and the count is regarded as the most thorough yet made. It revealed the presence of 7,921 individuals on the four feeding grounds maintained by the Biological Survey, 679 on two State feeding grounds, and 11,255 spread out over the adjacent region, including national forest areas, and easily counted from the air because of a background of snow (Report of the Bureau of Biological Survey for year ended June 30, 1932). The total of 19,855 in the herd compares with 19,238 counted five years before, so that the herd appears to be maintained in almost stationary numbers.

Rodents of the Semipalatin District of Kazakstan. A paper on these rodents by B. A. Kuznetzov (*Bull. Soc. Nat. Moscou*, 41, Nos. 1–2) results from an expedition to investigate the fur trade of this part of Siberia and to study the mammalian fauna of the area, the latter only being discussed here. The distribution of the species of wild animals is shown for the various districts, some of which have mountains under perpetual snow, while others are mostly steppe. The zonality of vegetation is not necessarily accompanied by one in the distribution of local species, high mountain and steppe forms of animals often being found together. The bulk of the work is devoted to interesting systematic and biological notes on the rodents of the area. The author asserts that some forms, such as the alpine hare (*Lepus timidus*, L.) and the squirrel (*Sciurus vulgaris*, L.) are decreasing in numbers through man's activity, while others such as *Cricetus Cricetus*, L. are increasing as a result of cultivation following forest clearing.

Antennal Secretion in Insecta. Although in a few exceptional cases the antennæ of adult insects are modified for special uses such as grasping the female, they have hitherto been regarded as entirely sensory in function. In this connexion a number of antennal receptor organs have been described which are believed to respond to various external stimuli and are accordingly said to be either tactile, olfactory or auditory (Johnston's organ). It is therefore of some interest to note the recent discovery by Mr. S. Maulik (*Proc. Zool. Soc. London*, pp. 943–956; 1932) of a new and complicated type of antennal organ which he considers to be secretory in function. The organ occurs in the enlarged eighth antennal segment of the males of certain chrysomelid beetles of the genus *Agetocera*. It consists of an internal chitinised tube which opens by a well-marked external orifice on to a specialised surface. Two types of organ have been distinguished, a long, tapering tube giving off into the surrounding tissue innumerable minute unbranched tubules of identical diameter, and a larger more or less dichotomously branched tube the ramifications of which penetrate the surrounding tissue in tubules of continually decreasing diameter. The ninth segment is also modified in sympathy with the eighth but the connexion between them is unknown. The probable function of this organ is the dispersal of certain products of secretion in relation to some aspect of sex activity at present unknown.

Daffodils, Narcissi and their Hybrids. The classification of garden plants presents many difficulties which do not beset the systematy of wild flowers. The care and selection given by gardeners is responsible for new forms which become very numerous as years go by. Travellers also bring new species or varieties which add greatly to the confusion of classification whilst enriching the beauty of the garden. "A Monograph of *Narcissus*, subgenus *Ajax*", recently published by Mr. H. W. Pugsley (*J. Roy. Hort. Soc.*, **58**, pt. 1, 17–93, Feb. 1933) clears up many difficulties connected with the identity of several different types of daffodils. The history of the sub-genus *Ajax* is traced from the sixteenth century, when many varieties were already in cultivation. Two main sections of the sub-genus are now recognised · *Cyclaminopsis* and *Pseudo-narcissus*, and the latter is subdivided into six series: *Minores*, *Lutei*, *Vulgares*, *Nobiles*, *Albiflori* and *Bicolores*. Twenty-seven species are described with such detail as to be useful to the botanist, the gardener, or the geneticist.

Inheritance of Grain Colour in Oats. Various investigators, beginning with Nilsson-Ehle, have found two factors present for black grain colour in oats. In crosses carried on at the Scottish Plant Breeding Station, Mr. William Robb (*J. Genetics*, vol. 26, No. 2) finds that the varieties Bell, Black Mogul, Black Tartarian and Sir Douglas Haig are homozygous for a single black factor, giving 3:1 ratios in crosses with white varieties. In the varieties Myrtle and Black Mesdag, however, two factors, *B* (black) and *G* (grey), are present, their formula being *B B G G*. *B* is epistatic to *G* and in crosses with white varieties an almost continuous series of grain colours is obtained, indicating a cumulative action of factors similar to that found in wheat. The variety Orion is found to be homozygous also for a third factor *B*, its colour formula being *B B B′ B′ G G*. The eleven white-grained varieties of oats tested were found to be homozygous recessives with the formula *b b b′ b′ g g*.

Cyclone Season in the South Indian Ocean. The cyclone season of 1929–30 is discussed by R. A. Watson and N. R. McCurdy in *Miscellaneous Publications of the Royal Alfred Observatory*, No. 12. This is the third publication in this series dealing specially with the cyclones of the western part of the South Indian Ocean, Nos. 7 and 10 covering the periods 1927–28 and 1928–29. The season under review appears to have been a remarkable one in many ways. In December the rainfall in Mauritius was nearly twice the previous highest, several places having the huge total of more than 60 in.—nearly three times the normal fall in London in a whole year. The synoptic weather charts showed numerous depressions which, although of considerable depth, were yet without the vigour of typical tropical cyclones; even among those classified as genuine cyclones, none was notably intense. The storm of September 23–27, 1929, near Chagos Archipelago, was exceptional, first in that it originated less than 5° from the equator, and secondly, in its being only the second recorded in Mauritius so early as September during the past 119 years. The most intense cyclone gave a wind force of 10 on the Beaufort scale, corresponding with an average speed of about sixty miles an hour, at Reunion on February 2, 1930, and the lowest pressure recorded on the charts (994·6 millibars) occurred on the same day at Reunion. Such a wind speed is not uncommon in deep depressions in the neighbourhood of the British Isles; the pressure scarcely merits the description 'low'; and the event well illustrates the moderate and anomalous character of this cyclone season.

Momentum and Energy in the Special Theory of Relativity. In *Current Science* (1, No. 8, Feb. 1933) Prof. A. C. Banerji, of the University of Allahabad, considers some of the difficulties which arise when an attempt is made to combine the special theory of relativity with the ordinary ideas of momentum and energy. If the invariant masses of two particles are respectively m_1 at A and m_2 at B, and their relative velocity is v, an observer at A will estimate the total momentum of the two particles as $m_2 v (1 - v^2/c^2)^{\frac{1}{2}}$, whereas the estimate of an observer at B will be $- m_1 v (1 - v^2/c^2)^{\frac{1}{2}}$. Similar discrepancies arise in the estimate of the energy. The attempt to define the position of the centre of mass is subject to a similar difficulty, arising from the variation of the masses with their velocities, but also an additional difficulty arises from the ambiguity in the estimation of the relative distance.

Internal Conversion of γ-Rays. An account of the work of Mott, Taylor and Hulme on the internal conversion of γ-rays has recently appeared in these notes (NATURE, **131**, 99, Jan. 21, 1933). According to their results, the values of the conversion coefficient plotted against the frequency lie on one or other of two smooth curves according to whether the nuclear radiation is of dipole or quadripole type. The internal conversion data may thus be used for classifying nuclear transitions into two groups. In a paper by Ellis and Mott (*Proc. Roy. Soc.*, Feb.) the transitions of the thorium B and C bodies are studied from this point of view. According to a theory proposed by Gamow and largely verified by Ellis, the loss of an α-particle may leave the nucleus in an excited state which collapses, giving rise to a γ-ray. The number of γ-ray transitions from the excited levels is connected with the number of α-particles in the corresponding emission groups, which have been studied by Rosenblum. Knowing, then, the number of β-rays produced by internal conversion, the internal conversion coefficient may be estimated. The coefficients obtained mostly fit satisfactorily on the two curves. It is found that many of the transitions are of quadripole type and quantum numbers analogous to the azimuthal quantum number l are suggested for the levels.

Polarity of Hydrocarbon Vapours. McAlpine and Smyth (*J. Amer. Chem. Soc.*, Feb.) describe measurements of the dielectric constants of benzene, toluene, propane and propylene, all in the gaseous state. An important result is the absence of any change of polarisation with temperature in the cases of benzene and propane, which indicates that the increase previously observed with rising temperature in the case of liquids is due to decreasing intermolecular action. The zero moment found for the benzene molecule agrees with its symmetrical structure, and the zero moment for propane is consistent with the absence of moment in the higher members of the series and shows that any polarity in the C–C bonds, electrical dissymmetry caused by repulsion in the molecule or difference in electronegative character between the hydrogens on the primary and secondary carbons, is too small to measure. The small moments found for toluene and propylene are of the same magnitude as those which might arise from inductive effects in the molecules.

Efficiency of Power Stations. In a paper on "Power Station Efficiency" read to the Institution of Electrical Engineers on March 23, Mr. W. S. Burge discussed the processes involved in the generation of electricity from coal and examined the effects produced by 'releasing' the heat at various temperatures. The main factors connected with the efficiency are four. The first shows how it varies with the steam pressure and the vacuum conditions. The second shows whether the maximum efficiencies of the various components forming the plant all occur at the same time or not, and the last two the effects of regenerative feed heating and superheating. The influence of the present physical limitations of the properties of metals, owing to the high temperatures used in practice, has also to be considered. The advances in the design of turbo-alternators in recent years have been so rapid that machines are now made which run at 3,000 revolutions per minute and have a capacity greater than 100,000 horse power. In the United States, it has been proved that when powdered coal is used, automatic control is more desirable than employing workmen. In one very large installation there, it is the habit of the 'watch' engineer to visit his boiler house only twice during an eight hour shift, although there is no one else in the boiler house. Mr. Burge considers that with no extension of steam conditions beyond about 650 lb. pressure per sq. in. and a temperature of 850° F., there is still wide scope for progress by making the plant item efficiencies have their values more nearly at the same time and thus improving the operating conditions. In his opinion, there is little scope for efficiency gain by using higher steam pressures and temperatures. Concentrated effort based on pressures of about 650 lb. pressure per square inch will produce the quickest and the best returns on the capital expended.

Astronomical Topics

Canals on Mars. An article by H. Boyd Brydon on this subject has recently appeared (*J. Roy. Ast. Soc. Canada*, Feb. 1933). It is in the main a discussion of E. M. Antoniadi's recent volume on Mars, and gives reasons for differing from his conclusion that all the narrow straight markings on the planet are an illusion.

The article quotes the following sentence from G. W. Ritchey describing certain observing sites (including Flagstaff): "The conditions of atmospheric definition and transparency are at least as much superior to those at Mt. Wilson as the latter are to the average conditions at the important observatories of northern Europe and the United States. The overwhelming impressiveness, the incredible tranquillity of the night sky seen at these very high semi-desert sites are beyond all description and imagination."

It is noted that the equivalent focus of the camera used at Flagstaff for Martian photography is 180 ft. Statements are quoted from Dr. Slipher that the photographs confirm the drawings as to the existence of a network of dark linear markings, sensibly uniform and continuous along their length; the photographs include a few double canals, but these are exceedingly difficult objects.

It is pointed out that M. Antoniadi lays undue stress on the fact that some drawings of the canals do not conform strictly to the laws of perspective.

Origin of the Solar System. A note in the Astronomical Topics in NATURE of November 5, 1932, gave some account of articles by A. C. Gifford on the above subject that appeared in *Scientia* last year. The note suggested that in giving the views of Sir James Jeans as to the age of the planetary system, thousands of millions of years should be substituted for the value millions of millions, stated in his articles. Mr. Gifford now quotes a passage from Sir James Jeans's earlier writings which certainly does suggest that he then assigned a more remote epoch for the stellar appulse than a few thousands of millions of years ago. Since that passage was written, much work has been done by cosmogonists in endeavouring to determine the age of the earth and the other planets. Their work is based on both astronomical and geological considerations, notably on a study of uranium and the products of its disintegration. The results are summarised by Dr. Harold Jeffreys in his book "The Earth"; the maximum estimate is about twelve thousand million years, the minimum one about a tenth of this. It is evident that Sir James Jeans now accepts these estimates; his article on Cosmogony in the "Encyclopædia Britannica", 14th edition (1929), vol. 6, p. 492, concludes as follows: "Our sun is a member of a colony of some thousands of millions of stars, the galactic stellar system. We do not know much about the number or arrangement of stars in the outlying parts of this system, but only in the dense central regions are stars at all likely to pass close enough to one another to produce planets. And here calculation shows that under present conditions planetary systems are only likely to be produced at the rate of about one in 6,000 million years. Thus our solar system with its age of only a few thousand million years is very possibly the youngest planetary system in the whole colony. Our terrestrial civilization, with only some 6,000 years of existence behind it, is almost certainly the youngest civilization."

***Annuaire* of the Observatory of the University of Belgrade for 1933.** This *Annuaire* is a useful volume for all observatories engaged in meridian work. It gives apparent positions, at ten-day intervals throughout the year, of 240 fundamental stars for which ephemerides are not given in any other publication. There are also tables giving true sidereal time and the reduction from true to mean; the short period terms in the nutation are given for every day. There is also a list of new minor planets.

Population Problems in the Pacific*

SINCE the publication of Rivers's "Essays on the Depopulation of Melanesia" in 1922, much attention has been given to the population problem in the Pacific and the causes of the decrease in numbers of the natives. A discussion at the Sydney meeting of the Australian and New Zealand Association for the Advancement of Science afforded a welcome opportunity for taking stock of the advance that has been made in the interval towards a real understanding of the factors involved. So far as it is possible to draw any general conclusions from the observations which were reported in the discussion and the inferences drawn from them, it would appear that while the psychological factor, on which Rivers laid so much stress, is still regarded as of importance, there is a tendency to attach greater significance to food and the need for medical attention. On the other hand, it is evident that there has been some change—perhaps even in a considerable degree—in conditions since the time when Rivers's observations were made. Some of the populations appear to be approaching, or even to have attained, a state of equilibrium in their contact with Europeans. Where this is occurring, credit must undoubtedly be given to wise methods of administration.

The discussion was opened by Sir Hubert Murray, president of the Association, who was in the chair. In a communication on "Depopulation in Papua" he said that while there is no evidence of depopulation in general, there is a decline in the Eastern Division and the South-Eastern Division. The main causes he believes to be three—insufficient food-supply, disease and the passing of the old modes of life. His conclusion is that some tribes may succumb altogether, but the more resistant stocks will remain and their natural increase will be more than enough to make up the loss. He advocated the introduction of new foods rich in vitamins, and the extension of the activities of medical officers.

Mr. E. W. P. Chinnery, of the New Guinea administrative service, pointed out the necessity for a census and Mr. F. E. Williams, Government anthropologist of Papua, while arguing that the administrator must apply the conclusions reached by science, suggested certain lines of action which should be taken forthwith by the administration while scientific workers are continuing their investigations. The factors in the depopulation problem, he holds, fall into two classes, pre-European and post-European. The pre-European factors, native warfare, sorcery and certain sexual practices, act as checks and must be removed. Among post-European factors are introduced disease and the loss of interest in life, these being of major importance, while of minor importance are increasing masculinity and the decline of polygamy. He stressed the importance of the limitations of the food supply.

Prof. Raymond Firth in "Indices of a Stable Population" dealt with the population of Tikopia, where the factors of fertility are outstripping those of morbidity and the population is increasing. This is due chiefly to the fact that former checks are inoperative. Hence pressure is being put on the food supply, much to the consternation of the old men. This last aspect of the problem of population was also considered in a communication of a more general character from Prof. S. H. Roberts, who laid stress on the economic factor and advocated the intervention of the administration to secure economic regeneration. Dr. Ian Hogbin, dealing specifically with the causes of depopulation, examined the contention that the islands were becoming depopulated before the arrival of the European on the scene, and the actual evidence for an increase in the death-rate and its causes. Prof. J. Macdonald Holmes, taking into account the number of extra-territorial peoples, especially Indians and Chinese, now resident in the Pacific, also dwelt on the economic factor, and inquired whether trade relegated the native to an inferior position and broke down tribal or family organisation.

A valuable communication on "The Medical Sciences in Relation to Depopulation" by Dr. R. W. Cilento followed. He divided the effects of European intrusion on native races into three stages. In the first, attack by arms, by new diseases and by dislocation of tribal life caused an enormous decline. This stage has long passed in the Pacific. The second stage is one of partial adjustment, when the European seeks to impose his scale of values on the native. The native loses the safeguards of savagery and, as he fails to get a substitute, a state of disequilibrium follows. This is to be seen in many parts of Melanesia. Finally, either the factors for decline predominate and the native race disappears, or adjustment becomes gradually complete and the population begins steadily to increase. Of the causes of depopulation, by far the most important are disease and food deficiency. The psychological factor, Dr. Cilento believes, is not the cause of depopulation, but merely an effect. Mental lassitude and bodily weariness follow chronic disease and prevent anything but the most essential tillage of the soil, thus providing and accentuating a vicious circle by further impoverishing the diet. The attitude of hopelessness is not a primary condition resulting from the disruption of native custom. The best method of attacking the depopulation problem is by going to the root of the trouble, devoting more attention to medical services and improving native diet by providing foods rich in protein and vitamins A, C and E. The lack of fertility is correlated with the lack of vitamin E, in which native foods are especially poor.

Dr. W. M. Strong also dealt with this aspect of the problem in his communication on the "Nutritional Aspects of Depopulation and Disease". He stressed the importance of vitamins in the diet, especially of indentured labourers, and quoted cases in which beriberi and scurvy have been cured by changes of diet, while he thinks that even tuberculosis might be averted by the provision of good nourishing food. Influenza epidemics have always caused more deaths in Papua when they have followed a drought. He urged the cultivation of a greater variety of native crops.

Dr. T. Wi-Repa pointed out that since the last century, when it was feared the Maori would die out, the population has increased.

The work of the missions in relation to the question of depopulation both in the past and at the present time was discussed by the Rev. J. W. Burton and the Rev. J. S. Needham, who pointed out that the missions not only check harmful customs such as infanticide, but also provide new interests, such as organised games, which take the place of warfare.

---

* From the report of a discussion on "Population Problems", Australian and New Zealand Association for the Advancement of Science, Sydney Meeting, August, 1932. *Oceania*, 3, No. 1, 91–100.

The discussion closed with an important paper by Dr. A. P. Elkin on "The Cultural and Racial Clash in Australia", which in its broader implications has a bearing on native problems in a wider field than that with which it deals immediately. He pointed out that the coming of civilisation brought about a sudden change in the environment of the aborigines of Australia. Before the advent of the white man, the aborigines had reached an almost static condition of equilibrium, which was maintained by an intricate, but logical, system of social, legal, religious and technical customs, ensuring the cohesion, solidarity and persistence of the aboriginal race in its environment. The change worked by the coming of the white man has been almost as hard, objective, and inhuman as a geographical change. Tribal and horde grounds, which were associated with the past through sacred sites and beliefs, are used by the white man for his own purposes. Being unable to perform the initiatory, historical and totemic rites in the way and at the sites sanctified by tradition, the aboriginal feels that there can be no future for him and prepares to die. Being unable to adapt himself to this new environment, he has rapidly decreased in numbers. The Australian race is another example of a type so specialised and adjusted to one environment that it cannot adapt itself to another.

Thomas Norton and the "Ordinall of Alchimy"

AS one of the earliest alchemical books in English, the "Ordinall of Alchimy" is of much interest; Dr. M. Nierenstein and Mr. P. F. Chapman are therefore to be thanked for their exhaustive inquiry (*Isis*, **18**, 290–321; 1932) into its authorship. Ashmole, in his "Theatrum Chemicum Britannicum", is the chief authority for ascribing the "Ordinall" to Thomas Norton of Bristol, who was supposed to have flourished in the fifteenth century. Ashmole's evidence for the authorship of this anonymous poem was that "from the *first word* of this *Proeme*, and the *Initiall letters* of the *six* following *Chapters* [namely, 'Tomais Norton of Briseto'] . . . we may collect the *Authors* Name and place of Residence". As for the date of the book, there is the statement at the end of the seventh chapter: "In this yeare of *Christ* One thousand foure Hundred seaventy and seaven, This Warke was begun, *Honour to God in Heaven*".

Dr. Nierenstein and Mr. Chapman, from a consideration of the language of the poem, and of the authorities quoted in it, regard the date 1477 as, in all probability, correct; and Dr. Peter Haworth, whom they consulted, says that the "Ordinall" certainly belongs to the second half of the fifteenth century. The problem of authorship is, however, more confused. Dr. Nierenstein and Mr. Chapman say that Norton's name, in connexion with the "Ordinall", became known only in 1617–18, when Michael Maier mentions him as a master of alchemy who wrote in English verse, and published a Latin version of the "Ordinall" in his "Tripus Aureus". They do not, however, notice that (according to Mrs. Singer's "Catalogue of Latin and Vernacular Alchemical Manuscripts", **2**, 556–7; 1930) two fifteenth century manuscripts of the poem exist, in which the author is described as "T. N." This would appear to afford weighty support to Ashmole's 'cipher' theory; though it does not necessarily follow that "T. N." belonged to the well-known Bristol family of which he is usually described as a member.

Dr. Nierenstein and Mr. Chapman have very carefully and thoroughly sought out the records of the Bristol Nortons, and have constructed a genealogical table of the family, covering the relevant period, so far as is necessary to establish the interrelationship of those members named Thomas. There appeared to be four Thomas Nortons, and four only, for whom any case could be made out as possible authors of the "Ordinall". Thomas Norton I was alive in 1388, and may therefore be safely rejected. Thomas Norton II is equally ruled out, as his will was proved in 1449. As to Thomas Norton IV, he was certainly dead in 1479, and it is extremely unlikely that he was alive in 1477. There remains Thomas Norton III, who, as great-grandfather of the alchemist Samuel Norton (1548–1604 ?), would seem to have the best claim, since Samuel refers to his ancestor as an alchemist. However, Thomas III also is unacceptable to Dr. Nierenstein and Mr. Chapman, who state that he was a thoroughly disreputable character, according to the Bristol records, "avoiding divine service" and spending "sermon time in the afternoon at tennis and frivolous sports". His will was dated November 26, 1513, and the authors think that he must have died soon after.

The conclusion at which Dr. Nierenstein and Mr. Chapman arrive is that Maier and Ashmole were not justified in definitely ascribing the anonymously written "Ordinall" either to "Thomas Norton" or to "Thomas Norton of Bristol". While no fault can be found with this cautious statement, it yet seems probable that Maier and Ashmole were correct; and in view of the well-known character of many alchemists, it is perhaps surprising that Dr. Nierenstein and Mr. Chapman did not consider that Thomas Norton III—who, on chronological and other grounds, is obviously eligible—has a strong claim on the very grounds of his disreputability. E. J. HOLMYARD.

Prehistoric Society of East Anglia

AT the annual business meeting of the Prehistoric Society of East Anglia held on February 18, Dr. Cyril Fox, director of the National Museum of Wales, was elected president for the year 1933, Prof. V. Gordon Childe, vice-president, and Mr. G. Maynard, of the Ipswich Museum, general secretary.

After the business meeting, specimens were exhibited and papers read. Mr. R. N. Chandler sent an account of his researches during the past six years in the basal gravel of the Swanscombe Terrace of the Thames Valley, where he had obtained more than 200 implements belonging to Stages 1 and 2 of the Clactonian culture. Fully 50 per cent of the artefacts are cores of which the chopping tool characteristic of the industry may be considered a variety. One type of tortoise core now described for the first time appears peculiar to the Clactonian of Swanscombe, while another approximates to those characteristic of Crayford. Some of the cores are remarkable for their size and weight, two described weighing 16 lb. and 19 lb. respectively. Ten types of artefacts are distinguished and the series dealt with in the present paper, and in that published in 1929, illustrate all the types of Clactonian implements so far known at Swanscombe.

A communication from Miss N. F. Layard described the discovery in the Buttermarket, Ipswich, of bone implements beneath 9 ft. of soft gravel, and at a depth of 23 ft. from the surface. A bone needle with hour-glass perforation, a bone awl, the handle of some implement, and an antler tine perforated for suspension, were associated with a human tooth and fragment of jawbone. The objects were removed from the matrix by Miss Layard, personally, in 1899, and the circumstances carefully noted at the time. It was submitted that the needle corresponded with the broken-eyed needles found by M. Didon in the Abri Blanchard, Dordogne, in an Aurignacian deposit and other late palæolithic cave deposits in France, figured by Didon and by Lartet. Mr. J. Reid Moir stated that, if actually *in situ* in the deposit described, the specimens would be of Palæolithic age. Mr. M. C. Burkitt compared the finds with those made at the Wookey Hole, which were of Late Celtic age, and doubted their greater antiquity.

Lieut. K. R. U. Todd exhibited flint implements discovered in the alluvial beds bordering the south shore of the Orwell Estuary and submerged at high tide. One industry is characterised by long blades associated with burins; one was 137 mm. in length, while a hundred measured specimens gave an average length of 67 mm. Dr. Godwin's analysis of the peat on which certain implements of early Neolithic forms rested indicated a temperate climate of post-glacial, Atlantic type, whereas the similar long blade industry found on the north shore of the estuary and described by Mr. J. Reid Moir, had been tentatively referred to the Madelenian by Prof. H. Breuil, and the measurements of the present specimens from the south bank were very near those from the type station of La Madeleine. Mr. M. C. Burkitt and Mr. Graham Clark compared the industry associated with the floor in the peat with that at Lower Halstow, and emphasised the occurrence of burins in Mesolithic times. It has to be remarked, however, that there is more than one cultural horizon in the Orwell alluvial beds, and that it is now regarded as highly probable that the long-blade industry comes from floors at lower levels than those yielding the flints for which Mesolithic associations were claimed in the discussion.

Experimental Gob Fires

THE Safety in Mines Research Board has issued papers Nos. 75 and 76, concerning gob fires, written by T. N. Mason and F. V. Tideswell (London: H.M. Stationery Office, 1933. 1*s*. net and 6*d*. net). The first of these deals with the possibility of explosions in sealed-off areas in non-gassy seams, and the second with the possibility of the revival of heating by in-leakage of air. The experiments were carried out in a special building arranged for the purpose at the Experimental Station at Buxton. This building consists of a central chamber 30 ft. square and 9 ft. high to simulate a mine goaf, circumscribed by an air-course approximately 6 ft. wide by 7 ft. high. The chamber and air-course are connected by doors 6 ft. square capable of being closed, and in one corner of the air-course there is a centrifugal blowing fan.

The first group of experiments simulated a fire in the goaf in a pack situated centrally in the goaf chamber; with an open fire it was found that there was no possibility of the formation of an inflammable atmosphere; with an enclosed fire this was found to be possible, though no inflammable atmospheres were actually produced under the conditions of the experiments. The next set of experiments simulated a gob fire developed in a roadside coal pack such as would be caused by a partly crushed pillar with a waste area behind. The most dangerous condition was when the fire was supplied with air from a leakage from intake to return, which also partly ventilated the waste.

A third set of experiments simulated fires in dirt packs adjoining a waste, the dirt containing as usual in practice approximately ten per cent of coal. Apparently no explosions occurred, but it is not safe to conclude that such conditions would never lead to the formation of an inflammable atmosphere. Special emphasis is laid on the fact that if an underground fire is to be sealed-off, the sooner and the more quickly that operation is carried out the better. The maximum danger of the formation of an explosive mixture is immediately after the sealing-off.

Paper No. 76 shows that an in-leakage of air which causes the oxygen content to rise to as little as 5 per cent (in one case 3 per cent only) usually results in a marked increase in activity of the heating. It was found that when the temperature had fallen so low as 75° C., a fire may be revived under suitable conditions. It is pointed out that although the flame of a safety lamp is extinguished when the oxygen in the air has fallen below 17 per cent, that is no guide whatever in determining whether an atmosphere is capable of extinguishing a gob fire or not.

Calendar of Nature Topics

Second Buchan Cold Spell

April 11–14.—Of the six 'cold spells' enumerated by Dr. A. Buchan, the second, April 11–14, receives the least support from either fact or folk-lore. There appears to be no popular saying associating these days with a fall of temperature, and the average daily temperatures at Greenwich from 1841 until 1930 do not reveal any marked cold period in April. An examination of the figures for the individual years at Kew Observatory from 1881 until 1923 showed that April 11–14 had been more often above the temperature to be expected at this season than below it. A different series of years might give a different result, but the inference is clear that Buchan's second cold spell has no real existence in London.

Spawning of Frogs, and a Remarkable Tadpole

The factors which determine the time of the spawning of frogs, the temperature of the air or the temperature of the water of the spawning pond or what not, have not been determined (so far as we recollect), but the range in time of the incidence of spawning suggests that the main factors might be readily discovered. In Hampshire, Gilbert White's earliest record of frogs spawning was February 28, his latest March 22; in Sussex, William Marwick's corresponding dates were February 9 and April 10; and in Cambridgeshire, Leonard Blomefield found a shorter range, March 4 to March 25, the average of nine years' records being March 16.

These observations relate to the common frog (*Rana temporaria*) in England, but in India spawning takes place about the same time, and the discovery of the eggs of *Rana afghana* in the Khasi Hills towards the end of March 1930, enabled Dr. S. L. Hora to describe the development of the curious suctorial disc by which the tadpole adheres to rock surfaces in the rapid streams in which it lives (*Trans. Roy. Soc. Edinburgh*, **57**, 469; 1932). The sucker is formed from the posterior lip of the tadpole, a lunate callous band on the under surface of the body, and lateral folds of skin which at first include the cement organs, although these disappear as the disc becomes functional. Dr. Hora thinks that the origin and development of the sucker can be explained by a series of small and gradual changes induced by recognisable factors in the environment, such as the speed of the current in which the tadpoles found themselves. The stages in the development of the disc are not necessarily correlated with the size of the specimens, as if the relative swiftness of the stream at different points provided the stimulus for the development of the disc.

Fish Cultivation in the Philippines

During April and extending to June or July occurs the spawning season of the most important of the sixteen hundred species of fishes recorded from the Philippines—the bañgos or milk-fish (*Chanos chanos*). It is by far the most common fish in the Manila market, and that because it is the product of a fish-pond industry in which a vast amount of capital, estimated at 45 million pesos, has been expended. Somewhat resembling a herring in shape and colour, though far exceeding it in size, this shiny silvery-white fish with pale steel-bluish back owes its value to a combination of qualities. It grows rapidly and may reach a length of three to four and a half feet; it is amongst the most prolific of fishes—a 30 in. female contained a little more than 3,000,000 eggs, a 44 in. specimen 5,700,000 eggs; it is wholly vegetarian and highly palatable; it is one of the few marine fishes adaptable to artificial cultivation in salt- and brackish-water ponds; and its fry is easily captured in enormous numbers (Adams, Montalban and Martin, *Philippine J. Sci.*, Jan. 1932, p. 1).

The first fish-ponds were tidal and were cut off from the sea except for an opening through which fry could enter but could not return to the sea. That uncertain method of stocking has been replaced in the more advanced fish-ponds by deliberate collection and transference of fry to specially designed ponds. A 10-hectare fish farm should accommodate 25,000–30,000 fry, at the rate of 50 fish to a square metre of pond; from these about 15,000–18,000 will reach the fingerling stage, which is transferred to growth ponds; and the final harvest may be reckoned at 9,000–11,000, or 900–1,100 per hectare. Although the bañgos reach quite a large size in the ponds, they never become mature, and breed only in the open sea.

Societies and Academies

LONDON

Physical Society, Feb. 3. F. J. W. WHIPPLE: Relations between the combination coefficients of atmospheric ions. The principal object of the paper is to put forward for consideration a formula, $\eta_{12} - \eta_{10} = 4\pi e w_1$, which indicates that the combination coefficient η_{12} for small ions and large ions of the opposite sign exceeds the coefficient η_{10} for small ions and uncharged nuclei, and further that the difference between the two coefficients depends on the mobility w_1 of the small ions. The experimental evidence for the formula is discussed as well as possible applications. G. P. THOMSON, NORMAN STUART and C. A. MURISON: The crystalline state of thin spluttered films of platinum. Films of platinum spluttered in various gases have been examined by the method of electron diffraction. They often show patterns which indicate that the small crystals are oriented with one face parallel to the surface of the specimen, the crystals being otherwise at random and in many cases the crystals are very small, of the order 5×10^{-7} cm. Some films of platinum dioxide showed crystals of the order 2×10^{-7} cm. E. V. APPLETON and R. NAISMITH: Weekly measurements of upper atmospheric ionisation. The ionisation is 2·2 times as intense on a summer noon as on a winter noon, and, in general, was slightly less in 1932 than in 1931. This reduction is due to the approach of sunspot minimum, and, with other evidence, suggests that the ionising agency from the sun varies by as much as 60 per cent during the 11-year solar period. Although ultra-violet light is accepted as the major ionising agency, thunderstorms most probably constitute one of the subsidiary causes, as previously suggested by C. T. R. Wilson. J. A. RATCLIFFE and E. L. C. WHITE: An automatic recording method for wireless investigations of the ionosphere. The Breit and Tuve method is employed, and both the transmitter and the time base at the receiver are synchronised with the A.C. mains. Some specimen records are reproduced and are used to illustrate the normal diurnal variation of equivalent height. Attention is directed to a common 'abnormal' occurrence of increase of ionisation in the lower (E) region, during the hours of darkness, without a corresponding increase in the upper (F) region, due possibly to storm clouds, as suggested by C. T. R. Wilson.

EDINBURGH

Royal Society, March 6. J. B. SIMPSON: The late-glacial re-advance moraines of the Highland border west of the River Tay. Following upon the westward retreat of the last general ice-sheet from the central valley of Scotland and an incursion of the sea when the land level was at least 90 ft. lower than now, considerable re-advances of the ice occurred on at least two occasions. The first of these is described in detail for the district between Dunblane and Perth. From varved clays the period between the retreat and the re-advance is estimated at 640 years. This re-advance is correlated with the Ra moraines of Scandinavia. A later re-advance is marked by striking terminal moraines in the Upper Forth Valley and Loch Lomond areas. E. B. BAILEY: Help from America in reading Scottish tectonics. It is now often possible, by adopting American technique, to determine on mere inspection whether a particular rock is upside down or right way up. This possibility exists wherever a rock shows graded bedding, since in each individual bed with a contrasted coarse and fine margin, the coarse margin is the older. Also wherever current bedding involves an erosional contact, the eroded rock is the older. Many fruitful applications of these two principles during recent years in Scotland and Northern Ireland were outlined. Among other discoveries it has been revealed that thinning, in the Ballachulish district, has taken place preferentially in the normal limbs of large-scale recumbent folds. This opens a new department of tectonics, wherein drag is more important than thrust. T. KERR: The pituitary in *Lepidosiren* and its development. Development is peculiar in that the external rudiment (ectophysis) of the gland originates as in teleosts and amphibians in the form of a solid ingrowth, but unlike these, later develops a cavity. The cavity persists in the adult, dividing the anterior lobe from the intermediate and posterior lobes. The adult organ is unlike that of any other class; its structure and histology are considered.

PARIS

Academy of Sciences, Feb. 20 (*C.R.*, **196**, 523–580). C. MATIGNON and M. SÉON: The action of steam on heavy petroleum oils and on certain cyclic hydrocarbons. Zirconia was used throughout these experiments as catalyst. Details of the results obtained with metaxylene, cyclohexane, cyclohexene, gas oil and mazout are given. The object of the work was to find an economical means of preparing hydrogen. A. BIGOT: The deformations of the Cambrian grits containing shingle in the neighbourhood of Cherbourg. PAUL DELENS and JACQUES DEVISME: Certain differential forms and associated metrics. N. ARONSZAJN: The decompositions of uniform functions. E. KOGBETLIANTZ: Laguerre's series. L. SANTON: Some results obtained with a supersonic blower. Study of the methods of measuring the velocities of air currents higher than the velocity of sound. With the hot wire anemometer, as the air velocity increases, the power dissipated first increases, passes through a maximum, and then decreases. J. LERAY: The movement of a viscous liquid filling space. JEAN LOUIS DESTOUCHES: Superquantification and mechanics in abstract spaces. F. HOLWECK and P. LEJAY: Contribution to the compensation of the European gravimetric network. J. DELSARTE: The binary ds^2 and the problem of Einstein. PAUL LE ROLLAND and PIERRE SORIN: A new method of determining the moduli of elasticity. MLLE. M. QUINTIN: Study of the temperature coefficient of the chain: copper, copper sulphate; mercurous sulphate, mercury. Data are given for a temperature range of 0°–46·5° C. J. E. GARSSEN: The magnetic susceptibility of some mixtures of substances of large electric moment. The magnetic susceptibility of acetone-nitrobenzene and acetone-paranitraniline mixtures is not a linear function of the concentration. Whilst a chemical combination is not impossible, it is pointed out that another explanation is possible. PIERRE AUGER and GABRIEL MONOD HERZEN: The emission of neutrons by aluminium under the action of the α-particles. Mme. Irène Curie and F. Joliot have recently shown the presence of neutrons in the radiation emitted by aluminium under the influence of the α-rays, the proof being based on the measurement of the relative absorption in lead and paraffin. These results have now been confirmed by Wilson's method. The emission of neutrons by aluminium is much rarer than that of beryllium under the same conditions, but the general characters are the same. H. MURAOUR and G. AUNIS: The laws of combustion of colloidal nitrocellulose powders. LIGOR BEY, REZAT BEY and GABRIEL VALENSI: The titimetric determination of the sugars. Systematic study of the effects of variations of the working conditions in the titration of sugars with ammoniacal copper solutions. A. TRAVERS and LU: The volumetric determination of lead. The lead is precipitated by sodium hypochlorite as the dioxide and the latter determined iodometrically. PIERRE LÉVY: The halogen indices of the aleurite oils known as China wood oils. L. ROYER: The difference which exists between a mica and a clay with respect to the possible orientation of crystals deposited on them. PAUL GAUBERT: The properties of crystals of phlorizoside (phlorizine). MLLE. M. COLANI: Artificial ridges of the valves of lamellibranchs (Northern Annam). It is concluded that twenty deposits of shells of *Placuna placenta* found in Annam have been caused by neolithic man. MME. VORMS: The anatomical characters resulting from the arrest of development in galls. S. MAHDIHASSAN: The different symbionts of the cochineal insects producing and not producing wax. PIERRE GAVAUDAN: A certain correlation between the reversibility of the phenomena of cytoplastic instability and the spontaneous disappearance of the vital colorations of the vacuome in *Ascoidea rubescens*. RAOUL LECOQ: The rôle of B avitaminosis and of the food equilibrium in the utilisation of lactose by the rat. RAOUL P. MAY: The modifications observed in the spinal cord in the case of grafting or ablation of a rudimentary posterior paw in the embryo of *Discoglossus pictus*. MAURICE LECAMP: The induction of limbs and region of regeneration in *Alytes obstetricans*. PAUL WINTREBERT: The existence, in the blastula of amphibians, of a centre of mitogenetic induction, regulating development. ETIENNE WOLFF: A new direct teratogenic method allowing the production of monsters by means of electrolytic lesions. L. LEMATTE and E. KAHANE: Silica in the organism and the siliceous particles of the blood. It is probable that a part, at least, of the silica in the blood is of respiratory origin and that it is composed of siliceous dust resisting attack. G. DELAMARE: The generators of the primary helix of the body of the polyspiral spirochætes.

SYDNEY

Royal Society of New South Wales, Nov. 2. ALMA G. CULEY: Notes on the mineralogy of the Narrabeen series of New South Wales. The percentage of heavy minerals in the Narrabeen sediments is generally low. Zircon, rutile, tourmaline and picotite are constant constituents, while magnetite and ilmenite are commonly present. Garnet, apatite, monazite, spinel and hypersthene are peculiar to the northern sediments. Galena occurs in sandstones from Mount Victoria. Authigenic minerals recognised are: anatase in perfect crystals, accompanied sometimes by brookite, leucoxene and some secondary rutile, idiomorphic barytes, chalcopyrites and pyrites. Spherulites of calcite and siderite are present in several specimens. A sandstone from Bulli Pass has perfect quartz crystals developed in capillary cavities, and also imperfect quartz crystals resulting from the enlargement of quartz grains. A mineralogical relationship between the Narrabeen series and Kamilaroi system is suspected. F. P. DWYER and D. P. MELLOR: A note on the occurrence of β-cristobalite in Australian opals. Powder photographs have shown the existence of β (high) cristobalite in Australian opals of both the precious and common varieties. In only three cases, precious opal (*Tintenbar*), wood opal and altered diatomaceous earth, does the complete pattern of β-cristobalite appear. In all others a single broad band in the position of the most intense line of the β-cristobalite pattern appears. In these specimens the crystallites are extremely small. Scarcely any change in the diffraction pattern appears when the latter class of opal is heated at approximately 1,000° C. for several hours. When heated in the presence of potassium chloride, the crystals appear to grow, since after this treatment the broad band disappears and gives way to the sharp line pattern of β-cristobalite. M. B. WELCH: Moisture content of wood. It is essential, in order to avoid gaping joints and cracks, that wood should be thoroughly seasoned before use, and the only true indication of this condition is obtained by determination of the moisture content of the wood. Wood is continually in a state of swelling and shrinkage due to absorption or loss of moisture from the atmosphere, but only within small limits. The result of a large number of tests indicates that for Sydney an average moisture content of 13·5–14 per cent denotes properly seasoned timber. V. A. BAILEY. The quantitative theory of interaction between different species of animals. A mathematical theory of animal populations, arising out of the biological analysis of Dr. A. J. Nicholson, is described in outline. The fundamental equations of the theory are stated and certain of their consequences, biologically interesting, are mentioned. The variations of the animal densities near the steady state in a special non-continuous case are determined and shown to be represented by functions of the form $Ac^t \sin (\lambda t + B)$, where A and B are constants dependent on the initial densities, and c and λ are simple functions of the host-species' power of increase F, with $c > 1$

Forthcoming Events

Saturday, April 8

GILBERT WHITE FELLOWSHIP, at 2.30.—(Annual General Meeting in the Hall of the Art-Worker's Guild, 6, Queen Square, W.C.1).—At 3, Sir John Russell: "Modern Trends in Agricultural Science".

Monday, April 10

ROYAL GEOGRAPHICAL SOCIETY, at 5.—Discussion on "The Use of the New Grid on Ordnance Survey Maps", to be opened by Brigadier H. L. Winterbotham.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6 (Joint Meeting with the Institute of Transport).—C. J. Spencer: "Electric Trolley Omnibuses".

Wednesday, April 12

SOCIETY OF GLASS TECHNOLOGY, at 2—(in the Mappin Hall, The University, Sheffield).—Annual General Meeting.

Official Publications Received

GREAT BRITAIN AND IRELAND

Annals of the Solar Physics Observatory, Cambridge. Vol. 3, Part 2: Microphotometry of the Solar Spectrum from 4040 to 4390A. By Dr. R. V. D. R. Woolley. Pp. v+79–118. (Cambridge: At the *University Press.*) *7s. 6d. net.*

Report of the Marlborough College Natural History Society for the Year ending Christmas, 1932. (No. 81.) Pp. 72+7 plates. (Marlborough.) To Members, *3s.*; to Non-Members, *5s.*

Researches published from the Wards and Laboratories of the London Hospital during 1932. 29 papers. (London: H. K. Lewis and Co., Ltd.) *7s. 6d.* net.

City and County of Bristol: Bristol Museum and Art Gallery. Report of the Museum and Art Gallery Committee for the Period October 1st, 1931, to December 31st, 1932. Pp. 28+4 plates. (Bristol.) *2d.*

Proceedings of the Edinburgh Mathematical Society. Series 2, Vol. 3, Part 3, February. Edited by Prof. H. W. Turnbull and Dr. E. T. Copson. Pp. 151–230. (London: *G. Bell and Son, Ltd.*)

National Joint Industrial Council for the Flour Milling Industry. Technical Education Series, Pamphlet No. 9: The Wheats of Commerce. 1: *General Considerations. By Dr. E. A. Fisher and Dr.* C. R. Jones. Pp. 51. *6d.* net. Technical Education Series, Pamphlet No. 10: The Wheats of Commerce. 2: Commercial Wheat Classes. By Dr. E. A. Fisher and Dr. C. R. Jones. Pp. iii+53–104. *6d.* net. (London.)

Biological Reviews and Biological Proceedings of the Cambridge Philosophical Society. Edited by H. Munro Fox. Vol. 8, No. 2, April. Pp. 107–240. (London: Cambridge University Press.) *12s. 6d.* net.

OTHER COUNTRIES

Proceedings of the Imperial Academy. Vol. 9, No. 1, January. Pp. ii+30. (Tokyo.)

Japanese Journal of Physics. Transactions and Abstracts, Vol. 8, No. 2, February 10. Pp. iv+57–108+21–52. (Tokyo: National Research Council of Japan.)

Journal of Science of the Hiroshima University. Series A (Mathematics, Physics, Chemistry), Vol. 3, No. 1, December. Pp. 136. (Tokyo: Maruzen Co., Ltd.)

The Tôhoku Mathematical Journal. Vol. 36, Part 2, January. Pp. ii+189–397. (Sendai: Tôhoku Imperial University.)

University Observatory, Oslo. Publication No. 5: On the Theory of the Chromosphere and the Corona. By Svein Rosseland. Pp. 37. (Oslo: A. W. Broggers Boktrykkeri A.-S.)

Publications of the Observatory of the University of Michigan. Vol. 5, No. 4: The Elements and Ephemeris of Comet Dodwell-Forbes (1932n.) *By Allan D. Maxwell. Pp. 39–42. (Ann Arbor, Mich.).*

State of Connecticut. Public Document No. 24: Fifty-fifth Report of the Connecticut Agricultural Experiment Station, New Haven, for the Year 1931. Pp. xii+850+74. *(New Haven, Conn.).*

Geological Survey of Uganda. Memoir No. 3: The Volcanic Area of Bufumbira. Part 1: The Geology of the Volcanic Area of Bufumbira, South-West Uganda; with Notes on the Petrology and Economic Geology. By A. D. Combe and W. C. Simmons. Pp. xi+150+12 plates. (Entebbe: Government Printer.) *15s.*

Forest Bulletin No. 80: List of Trees and Shrubs for the Kashmir and Jammu Forest Circles, Jammu and Kashmir State. By W. J. Lambert. Pp. v+40. (Calcutta: Government of India Central Publication Branch.) 12 annas; *1s. 3d.*

The Science Reports of the Tôhoku Imperial University, Sendai, Japan. Fourth Series (Biology), Vol. 8, No. 1, February. Pp. 74+4 plates. (Tokyo and Sendai: Maruzen Co., Ltd.)

Meddelelser om Grønland udgivne af Kommissionen for Videnskabelige Undersøgelser i Grønland. Band 79, Nr. 4: The Godthaab Expedition 1928—Alcyonaria, Antipatharia and Madreporaria. By P. L. Kramp. Pp. 20. (København: C. A. Reitzels Forlag.) 1.00 kr.

Report of the Aeronautical Research Institute, Tôkyô Imperial University. No. 92: On the Transmissibility of Visible Light through a Cloud of Particles. By Daizo Nukiyama and Atusi Kobayasi. Pp. 307–338. 35 sen. No. 93: Hôbutumen no Onkyôgakutekino Seisitu ni tuite (On the Acoustical Properties of Parabolic Reflectors), Part 2. By Kôzi Satô and Masaaki Sasao. Pp. 339–356. 25 sen. Tôkyô: Koseikai Publishing House.)

Scientific Papers of the Institute of Physical and Chemical Research. No. 409: Vitamin C in Japanese Green Tea. By Masataro Miura and Michiyo Tsujimura. Pp. 129–144. *20 sen. No. 410: On the* Antiscorbutic Factor in Commercially Sterilized Milk and Japanese Green Tea—An Experiment upon Monkey. By Masataro Miura and Nagayo Okabo. Pp. 145–161. 25 sen. Nos. 411–413: On the Minor Constituents of Thermoluminescent Calcite, by Shin Hata; The Absorption Spectra of Naturally Coloured Fluorites, by Jun Yoshimura; Reactivation of the Blood Forming Action of Liver by Constituents of Gastric Mucosa, by Fumito Inukai and Waro Nakahara. Pp. 163–188. 40 sen. (Tokyo: Iwanami Shoten).

Canada: Department of Mines: Mines Branch. Anhydrite in Canada: Occurrence, Properties and Utilization. By L. Heber Cole and R. A. Rogers. (No. 732.) Pp. v+89+5 plates. (Ottawa: F. A. Acland.) 20 cents.

CATALOGUES

Microscopical Preparations: Zoological and Botanical Material. (Catalogue A, eighth edition.) Pp. 112. (Manchester: Flatters and Garnett, Ltd.)

Colorimetry and Nephelometry. (Section E33.) Pp. 15. Moll Thermopiles and Vacuum Thermocouples. (Thermo 33.) Pp. 4. (Delft: P. J. Kipp and Zonen.)

Books on Various Subjects in New Condition at much Reduced Prices. (No. 465.) Pp. 24. Catalogue of a Portion of the Library of the late G. Lowes Dickinson. (No. 466.) Pp. 24. (Cambridge: Bowes and Bowes.)

History as Science

It is given to few Commissions to earn such widespread approbation of their report as has been deservedly afforded to that of the Lytton Commission on the Manchurian dispute. Even the authoritative tributes to its fairness and impartiality from all over the world did not, however, avail to prevent a charge of bias being brought against it in the House of Commons. That such a charge could have been made is evidence of the lack of historical perspective which characterises so much of our political life to-day and so often obstructs progress towards a new international order, and above all persists in regarding as a moral issue what is now only a question of practical policy.

If this absence of historical perspective has made politicians so inept at interpreting the facts of a political situation to-day, so blind to fundamental realities, it has had no less serious consequences among the advocates of technocracy who have been eloquent of late. A grasp of the fundamental fact that the advent of power production has revolutionised the whole position of man in relation to production, and shaken his economic and social structure to its foundations, has not prevented many of its exponents from largely ignoring human values and human factors in the technical control of production and distribution which they develop. Science is only one of the factors concerned, the scientific method only one of those employed by man in his slow advance; and history affords no justification for the neglect of other methods, or for the assumption that mechanical science by itself can solve all the problems with which man is confronted. The same mistake is made to-day as was made by Bacon, who thought that the "sovereignty of man lay hid in knowledge" and that scientific discovery would ensure the fortune of the human race. Three centuries have barely yet taught us how false and dangerous is the assumption that the knowledge of how to use knowledge goes hand in hand with the growth of knowledge.

There is, in fact, something strangely similar in the attitude of those politicians who desperately strive to revert to eighteenth century ways, and ignore the immense change which has come over mankind in the last century, and in that of those who see in science a sole and sufficient guide and imagine that all man's activities can be planned on scientific lines. Each alike lacks the sense of realities and of values which the study of history is so well able to impart, and it might be fair to place the responsibility of some at least of our difficulties on the neglect of history by our politicians and men of science alike, and on their consequent failure to interpret aright the course of present-day events.

At a time when the importance of studying the human factor is being more and more realised, when men are turning against an economic system in which increased productive powers only lead to more widespread unemployment and want, the qualities of imagination and sympathy which are essential to the understanding of history are in great demand in the affairs of society or State. The very demand and provocation of the humaner qualities which history makes, renders it an invaluable counterpart to the physical or mechanical sciences. Prof. Pollard is surely right when he urges that history is the highest form of science because its subject matter is the highest form of Nature, and that it is not commonly regarded as a science because it is too complex and too human for summary treatment by axioms, rules and formulæ.

If, however, history is not an exact science, it has much in common with the exact sciences. Dr. Tennant, for example, in the "Philosophy of the Sciences", claims first place for history in systematic order of departments of science, and asserts that it gives a far more adequate mirroring of reality than the abstract schemes of the higher sciences. Its collection of data demands qualities akin to those required of every searcher after truth whatever his field of inquiry. It is in the critical interpretation of the data acquired that history calls for qualities which are so admirably fitted to redress the balance, and in the humanisation of methods of controversy history may render its greatest service. Only by its guidance can we understand the causes of the religious, moral, political, social and economic environment in which we live. Knowledge of public action in the past provides the best means of understanding public action in the present and the surest guide for the exercise of political power. The study of history provides one way of joining to the mass of human knowledge the wisdom which alone can sort out the issues and permit beneficial action. Moreover, history, being both a science and an art, requiring a scientific analysis of materials and an artistic synthesis of results, calls for just that balance of scientific and impartial judgment, and imagination and sympathy in interpretation, which are at the root of wise administration and constructive policy.

History, though more complex, is not in fact less capable of scientific treatment than physics or chemistry, and, apart from providing a background against which alone political issues can be understood or viewed in a true perspective, its study encourages the scientific spirit in which alone political issues can be profitably examined. It is for this more especially that General Smuts has made such eloquent pleas. Prof. Pollard again has pointed out, for example, that a course on the history of London would be the first introduction to the scientific investigation of its present-day problems of local government, the vastest problems of the kind with which the human intellect has ever been called upon to deal.

This spirit we search for in vain, for example, in the recent debate on the arms embargo. We see no signs of any policy beyond that calculated to serve the narrowest exigencies of the moment—no regard to the question of world order and international action, no facing of the problems which must be faced once at least if a community of nations is to demonstrate its determination not to allow the old methods of irrational force to be introduced, no hint of the impartial and scientific survey of the facts of the particular situation carried out by the Lytton Commission and before that by the Institute of Pacific Relations. The expediency which dominated the debate has no room for realism, for the fearless facing of facts, for the scientific inquiry and deliberate co-operation which alone stand between us and world disaster.

Leaving aside the fact that a study of the history of science itself often suggests exceedingly fruitful lines of research, it should be clear that science and history have a joint contribution to make to our national and international needs which we neglect at our peril, and which it is the duty of the scientific worker as of the scholar of history to emphasise with instant eloquence. Bacon's vision of man "that will live and be a citizen of the world" in "De Augmentis Scientiarum" holds out our only hope of survival, and it were idle for science apart from history to seek to enforce the lesson.

Granted the wide fields such as politics, human biology, sociology, economics and psychology, into which the application of scientific methods is long overdue, such methods alone will not bring us the solution we desire. Even when such fields of knowledge have been placed on a scientific basis, there will remain the problem of human nature, and the study of human affairs by the application of physical formulæ alone is more likely to lead to mental confusion than to order. Scientific methods assist us to ascertain and assemble our facts, to clear our minds from passion and prejudice, but they can lead us to little of the rudiments of justice, ethics, logic or literature, though it must not be forgotten that the scientific attitude of mind may even yet prove to be a much more humanising element than might at first be expected when we think of it in terms of a struggle with the forces of Nature.

In the perspective and sense of values, the appraisement of human factors which the study of history engenders, we are able to assess correctly the position and responsibility of science. From this point of view we realise that the failure of the scientific worker to accept responsibility for the consequences of his discoveries inevitably means that he must accept the repression or suppression of certain aspects of scientific truth if the human race is to survive. If his citizenship is subordinated to his science, and the growth of an international civic sense does not keep pace with the advance of knowledge, society must itself take measures to prevent the perversion of science to destructive purposes. Knowledge may require insulation and control in the same way that electric power is safeguarded and its use restricted to those who can use it aright.

We come back, therefore, to the problem of relating knowledge and power in the service of the community. If acceptance of civic responsibility by the man of science is a fundamental condition before the scientific expert can play the part in human government indicated, for example, in certain phases of the work of the technical committees of the League of Nations, universal suffrage cannot be tempered with science by the efforts of the scientific worker alone. The scientific expert will only take his rightful place in national and international government as the study of history leads both administrators and the electorate to appreciate the significance of current events and tendencies.

This is a problem of education—of imparting not merely knowledge but also understanding, in ensuring that responsibility goes hand in hand with power. It is in this sphere—the teaching of philosophy by means of examples, in supplying the needed touch of human nature, that the study of history is of supreme importance in the study of scientific politics. Imagination and insight are here as essential as in the equipment of the man of science. History, as Prof. Pollard has said, is a matter of sense as of science, of feeling as well as of fact, and it is because history is not felt that citizenship is feeble. We cannot understand why men acted unless we know how they felt; and in discovering where men failed in sympathy and understanding because they did not understand what others felt, and thus knew not what they themselves were doing, we came to the realities of history upon which good citizenship and a new world order are based. History, being both an art and a science, offers us the opportunity of harmonising the discovery and use of new knowledge in ways which permit the free expansion of the human spirit and the continuous amelioration of the lot of mankind. The scientific teaching of history, as well as the teaching of science as part of ordinary culture, are indispensable elements in that training and discipline through which alone man can acquire the self-command and the wisdom by which to regain control over events.

Chinese Medicine

History of Chinese Medicine: being a Chronicle of Medical Happenings in China from Ancient Times to the Present Period. By Dr. K. Chimin Wong and Dr. Wu Lien-Teh. Pp. xviii + 706 + 55 plates. (Tientsin: The Tientsin Press, Ltd., 1932.) G. dollars 7.50; 30*s.* net.

TO most people in Great Britain the whole story of Chinese medicine is contained in a legend and an anecdote. The legend is to the effect that, in China, a doctor is only paid for keeping his patients well, and never for attending and curing them when ill—a reflection, probably, on the old saying from the Chinese classics that "The sage does not treat those who are ill, but those who are well". The anecdote is the well-known story of the sick man who went out to seek a Chinese doctor with the fewest lanterns outside his door, it being alleged that one such lantern must be hung up for every patient who had died at the doctor's hands, and that, having at length discovered a physician with but one lantern to his discredit, he found to his chagrin that the doctor had previously attended but one patient.

These stories, apocryphal though they are, give a delightful hint as to the possible relationship between doctor and patient in the Far East, but they scarcely claim to tell the whole story of

Chinese medicine, and in the bulky and well-documented volume before us, Dr. K. C. Wong and Dr. Wu Lien-Teh (the latter, a Cambridge graduate) have endeavoured to present a connected history of medical science in China from the earliest times to the present day. To some extent the book is a misnomer, as it is far more truly a "Chronicle of Medical Happenings in China", as its sub-title suggests, than a history of Chinese medicine, nearly five-sixths of its pages being devoted to the progress of Western medicine in China since its introduction by missionaries and others at the beginning of last century. For this reason it is the earlier chapters of the book which will be read with the greatest interest, containing as they do the foundation principles upon which the system of ancient Chinese medicine was built.

In that system, accurate scientific investigation, as we understand it in the West, took little or no part, for it is a strange fact that although China has from the earliest days revered all forms of scholarship and has made noteworthy contributions in the realms of art, and literature, and political economy, she entirely missed the stream of human progress in the matter of applied science. Instead of accurate knowledge based upon experiment and research, we find strange philosophical concepts, superstitious beliefs, and magical practices mixed up with shrewd observations and records of the symptoms and progress of the more common ailments, and an extensive knowledge of herbalistic lore.

Ancient Chinese philosophy proceeded from a belief in the existence of two opposing forces, the *yang* and the *yin* (positive and negative, active and passive, hot and cold, etc.), and all functions of the body, and even the main anatomical organs, were classified under these two categories. At the same time, it was considered that there were five primary elements in Nature (metal, wood, water, fire, and earth), upon the harmonising of which peace and equilibrium depended; and disease was therefore regarded as a disturbance of this balance owing to the excessive activity of one or other of these primordial substances. The diagnosis of any complaint thus became a matter of deciding in the first place whether it was a *yang* or a *yin* disease, and, further, which of the elements was out of proportion to the remainder. Treatment was similarly directed to a restoration of this disharmony, and just as *yang* (or hot) diseases could only be cured by *yang* drugs, so also physical disturbances due to the action of one of the five elements could only be successfully remedied by medicaments of that group.

During the Han dynasty (206 B.C. to A.D. 220) Chinese medicine made marked progress, and a number of medical treatises were then written which are quoted to this day by old Chinese doctors. These works included essays and discussions upon various diseases, elaborate studies of the pulse (regarding the character and varieties of which innumerable Chinese volumes were to appear in later dynasties), and the first attempt to produce a materia medica. The study of medicine continued to develop during the next few centuries, and though the old Chinese doctors were sadly handicapped by their ignorance of anatomy and physiology, many of them gained an accurate, if empirical, knowledge of important medical facts. The famous Pen Ts'ao Kang-Mu (the monumental Chinese treatise on pharmacology published in the sixteenth century and comprising no less than fifty-two volumes) not only refers to the usage of such well-known drugs as sulphur, mercury, and rhubarb, but also mentions remedies like kaolin, chaulmoogra oil, and ephedrine, the value of which have only recently been studied by Western pharmacologists. The treatment of such diseases as cholera, leprosy, and syphilis, and the value of inoculation against smallpox were also well understood, and an occasional genius like the renowned Hwa-To even appears to have anticipated the discovery of anæsthetics and antiseptic surgery.

Such discoveries were but fitful, and were soon buried in accretions of quackery and superstition, and as the barriers that at one time guarded the right to practise medicine gradually disappeared, the prestige of the physician rapidly fell into disrepute and the Chinese doctor became nothing but a pedlar of useless and even ridiculous concoctions.

It was the arrival of Western physicians, and in particular the very valuable work carried out through the last century by a succession of devoted medical missionaries, which restored medicine to its rightful place in China, and the greater part of the volume under review consists of a detailed account of the work accomplished by these men and women in overcoming native prejudice and establishing hospitals and even medical schools in China. With the rapid changes that have taken place during the last thirty years, the Chinese educational authorities and other agencies are now taking the lead in this matter, whilst a noteworthy contribution has been made by the Rockefeller Foundation in the erection at Peiping of one of the best-equipped medical schools to be found in the Far East.

Biology and Philosophy

(1) *The Inequality of Man: and other Essays.* By J. B. S. Haldane. Pp. ix+295. (London: Chatto and Windus, 1932.) 7*s.* 6*d.* net.

(2) *Leben und Erkennen: Vorarbeiten zu einer biologischen Philosophie.* Von Prof. Gustav Wolff. Pp. 442. (München: Ernest Reinhardt, 1933.) 11.50 gold marks.

(1) PROF. J. B. S. HALDANE'S book is, as he says, a mixed bag. It consists of a number of essays, mostly short: and one piece of fiction (a thriller of correct pedigree, by John Buchan out of H. G. Wells). Some of the essays are no more than good popular journalism, some are more substantial, but all are worth reading. There is a certain unity of purpose running through them, making the book philosophical in the wide sense. This purpose is to consider the way in which scientific knowledge, or lack of it, affects human life and society. Civilisation cannot stand still but must either develop or decay. Which course it takes depends upon whether we use scientific knowledge to cut our own throats or to reorganise society. Many of the subjects dealt with by Prof. Haldane are of acute interest.

Among the more academic topics are criticisms of some of the views of Russell, Eddington and Jeans. The ordinary biologist, or any ordinary person, is afraid to dispute anything a mathematician says in case he gets snubbed for talking about mysteries beyond his comprehension. Prof. Haldane is free of such inhibitions and is therefore a valuable critic. There is just one point, however, where the reviewer would question the value of the criticism. Jeans argues that as the whole material universe is 'running down', it must have been wound up at some finite past time and must cease to run down at some finite future time. Haldane replies (pp. 165–170) that time is infinite and that the total number of different kinds of events is finite, though large, since the whole volume occupied by matter is finite and the numbers of protons, electrons and photons are finite. Therefore every possible combination of events, however improbable, must occur over and over again. It is a good debating point, but both arguments rest on the assumption that the universe possesses a determinate time axis along which we can extrapolate as far as we like. They assume that the four dimensional figure is like a cylinder with time parallel to its axis; whereas an expanding universe must be more like a cone. The apex, if it is an apex, is in the past, but there is nothing to show how to extrapolate our time axis beyond the brief period about which we have positive information.

(2) Prof. Haldane's book provides easy reading for a few hours, Prof. G. Wolff's heavy reading for many hours (and no index). Perhaps it is only insular prejudice, but the reviewer doubts if those many hours will be as well spent as those few. Prof. Wolff propounds and develops a 'vitalistic' philosophy. The issue between 'vitalism' and 'mechanism' is by now scarcely a live one. A man cannot be a one hundred per cent mechanist because he has to exclude his own mind from the mechanistic scheme; nor can he be a one hundred per cent vitalist unless he is a solipsist because he must allow some validity to the mechanistic scheme. The controversy really turns upon the minor question of where to draw the line, or else of whether there would be a line to draw unless the problem was misstated. Fortunately Prof. Wolff leaves no doubt as to where he draws the line, for he states his position at the very beginning. He considers that the living and the lifeless differ absolutely, and the difference is that living organisms are purposive or teleological while lifeless things are not (p. 19). The author does not appear to put forward any evidence for maintaining this radical division. Indeed the evidence all points the other way. The differences between a stone and a dog are obvious enough, but in the series, bacterium, filterable virus, bacteriophage, enzyme, inorganic catalyst, the difference between living and lifeless is hard to define. Moreover we must believe, if we believe anything, that at some time in the earth's history life developed out of something that was not living (cf. Haldane's essay "The Origin of Life").

Finally, if there is such a science as physiology, which many have doubted, a considerable part of that science consists in investigating by the methods of physics how it is that organisms and their parts carry out purposive processes. The physiology of the eye is an account of how it fulfils the function of sight, of how a certain pattern of structures and processes produces normal or efficient sight and how certain deviations from the pattern render the eye less effective for its purpose. The question of purpose is there throughout, but the methods are the orthodox methods of physics. It is true that the physiologist, like the engineer, makes use of terms and concepts that have no place in the classical theory of physics, as laid down by Descartes and Newton; but it is permissible to conclude that the classical theory can be revised and expanded, and not necessarily that physiology is no part of physical science.

Of course, if the natural world was split by a radical dualism such as Prof. Wolff assumes, then science would be impotent in its own domain and the philosopher might well disregard its efforts and construct a purely idealistic philosophy on subjective lines. This, in effect, seems to be what he does. In any event, the case for a purely idealistic method in philosophy is an arguable one, though the arguments do not convince everybody; but it is very doubtful whether the case is improved by pretending that what are really subjective concepts have been derived from biology.

A. D. R.

Early County Maps of England

Reproductions of Early Engraved Maps. 2: English County Maps in the Collection of the Royal Geographical Society. With Introduction and Notes by Edward Heawood. Pp. ii+14+Atlas of 21 Sheets. (London: Royal Geographical Society, 1932.)

THIS group of twenty-one reproductions, in black and white, of maps of England will be of great value to all interested in the history of cartography. The original maps were all printed from engraved copper plates; some of them were originally over-painted by hand in colours, but these admirable reproductions are necessarily made from unpainted copies. The twenty-one plates comprise one general map of England and Ireland, by an unknown author, dated 1594; nineteen county maps strictly so called; and one sheet of playing-cards, illustrated by miniature county maps. The county maps proper vary in date from Saxton's "Southamtonia" of 1575 to John Speed's version of Norden's map of Sussex, dated 1610; so that it may be said that the Royal Geographical Society has reproduced a selected group of the earlier county maps, and has not, in the present publication, reproduced any of the later and more detailed maps on larger scales, such as Roque's Surrey or Taylor's Hampshire.

An excellent feature of the present publication is that we are able to compare the work of different cartographers. Here we are given Saxton's Hampshire, which can be compared with Norden's map of the same county, on the same scale, of about twenty years later. Norden's map is more detailed but is not so pleasant or easy to read. We have also in this collection two versions of Surrey, Cheshire and Hertfordshire, and three of Sussex. One might construct a mathematical mean of some of these maps which would presumably be more reliable than any one of them.

The county maps reproduced include five by Christopher Saxton, the father of modern English mapping; three by John Norden, whose work is original and independent. Then we have Philip Symonson's map of Eastern Kent, published in 1596; and a series of seven maps, out of a known total of twelve, belonging to "a homogeneous series", of unknown authorship, dating from the early years of the seventeenth century, based generally on Saxton or Norden, with variations; then two maps prepared for Camden; two published by John Speed, copied in the case of Sussex from Norden, and in the case of Cheshire from Saxton, with some alterations. It is a rich cartographical feast.

The collection is accompanied by an introduction and detailed notes by Mr. Edward Heawood. There is much to be learnt from the remarks of this high authority, and many curious facts are brought out, with reference, for example, to the manuscript maps of William Smith, "Rouge Dragon"; or to the work of Symonson of Rochester; or to Norden's maps of nine counties, which were original productions and not copies from Saxton. Mr. Heawood tells us that the "anonymous" series, is, as regards the engraving, of the Dutch-Flemish school; and, as regards the material, is influenced by both Norden and Smith. He also remarks that although John Speed did not always acknowledge his almost complete indebtedness to Saxton or Norden, "in any case Speed did good work in assembling material otherwise scattered", and points out that Norden himself valued Speed's editorial work.

A small correction is required on p. 9, where Saxton's "Southamtonia" is described as not dated; actually the date 1575 will be found under the coat of arms in the south-east corner.

Geographers owe a debt to the Royal Geographical Society for having thus rendered accessible facsimile copies of these important early county maps, some of which are of great rarity and some unique.

Short Reviews

Modern Methods in Quantitative Chemical Analysis. By Dr. A. D. Mitchell and Dr. A. M. Ward. Pp. xi + 178. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1932.) 6s.

In this book the authors have, as they clearly explain in their preface, deliberately selected from the large number of new methods available in analytical chemistry, in order to provide, in a conveniently limited space, details of one really sound analytical procedure for each of the substances discussed. They state the principles on which they have made their selections: that methods involving the use of the sintered glass crucible are preferable to those necessarily confined to "Gooch": that the methods should be as little empirical as possible: that they should have a definite bearing on analytical practice: and that they should not involve the use of inaccessible reagents.

After a description of "Some Methods of Wide Application"—methods involving the formation of positive halogen ions, the use of adsorption indicators and oxidation-reduction indicators, oxidation with ceric sulphate, the uses of organic complexes, and the use of the Clemmens Jones 'reductor'—there follow detailed methods for the quantitative estimation of sixty-seven different elements, radicals and compounds. The book has also a table of atomic weights, dilution tables and a full index.

The excellence of the book's general production, as well as the lucidity of all its expository matter and the catholicity of the authors' analytical 'taste', combine to make this a book quite literally indispensable to all engaged in the practice of analytical chemistry. It is much to be hoped that its circulation will warrant the frequent production of new editions and supplements. A. L. B.

Die geologische Erforschung Thüringens in älterer Zeit: ein Beitrag zur Geschichte der Geologie bis zum Jahre 1843. Von Prof. Dr. B. von Freyberg. Pp. xi + 160 + 8 Tafeln. (Berlin: Gebrüder Borntraeger, 1932.) 7.50 gold marks.

The variety in the geological formations of Thüringia, and the abundance of minerals and fossils in that part of Germany, led early to the study of its natural features. So long ago as 1710, Buttner published his "Rudera Diluvii testes", which was based on observations in Thüringia; and in 1756 J. G. Lehmann gave a good description of the stratified rocks around Mansfeld, thus producing a pioneer work in stratigraphical geology. In 1761 G. C. Füchsel published a remarkable account of the geology of the country, with new ideas well in advance of the time; while between 1755 and 1773 J. Walch issued the first important large treatise on fossils. In 1820 Baron von Schlotheim's "Petrefaktenkunde" made much advance in the modern study of fossils; and in 1822 K. E. A. von Hoff began the publication of his classic work on the explanation of geological phenomena by the study of changes now taking place on the earth's surface, which was a precursor of Lyell's "Principles of Geology".

In the new volume now before us, Prof. B. von Freyberg gives an excellent account of these and other achievements of geologists in Thüringia up to the year 1843. It includes a table showing the successive advances in knowledge of the stratigraphy of the country, and is illustrated by several beautiful portraits, of which that of von Hoff will particularly interest English readers.

The History of the Phlogiston Theory. By Dr. J. H. White. Pp. 192. (London: Edward Arnold and Co., 1932.) 6s. net.

This little book, originally a thesis for the Ph.D. degree of the University of London, is written, according to the author, to dispel the mists which are gathering around our conception of the phlogiston theory: indeed, definite misstatements with regard to it are becoming increasingly common. In any event, it is useful to have in one book the full story of the wax and wane of the theory through a century of chemical history. At the outset of the eighteenth century, alchemy was flourishing and the philosopher's stone was still eagerly sought. By the end of it, quantitative chemistry had begun, chemical combination was being understood: chemistry had advanced in spite of the phlogiston theory, the work of Lavoisier had overthrown the doctrine of Stahl.

Dr. White divides his book into a dozen chapters and gives a number of references; he has been to the original material in the British Museum Library. He ends, as is proper, with some definite conclusions, of which perhaps one of the most significant is that the phlogiston theory did little to stimulate research. This must always be the prime object of any theory; even if a hypothesis be proved to be wrong, it will not have been made in vain so long as it has been productive of experimental work. We regard the essay as a useful and a fruitful one, which will repay perusal by serious students and others interested in the past of chemical science.

Die gruppentheoretische Methode in der Quantenmechanik. Von Prof. Dr. B. L. van der Waerden. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R. Courant, Band 36.) Pp. viii + 157. (Berlin: Julius Springer, 1932.) 9.90 gold marks.

The difficulties of group theory are no doubt considerable, but here is a book of reasonable size which gives a fairly elementary account of the application of the theory to quantum mechanical problems. It is now well known that Schrödinger's wave equation leads to the discrete energy levels for the hydrogen atom required by Bohr's theory of 1913, but here it is shown how group theory, when applied to angular momentum in connexion with the wave equation, leads to important conclusions as to the energy levels of more complicated systems. Quantum numbers appear in an almost magical manner.

The book may be warmly recommended to the theoretical physicist, but the experimenter may wonder whether the principles of symmetry which are involved in the group treatment could not be developed and applied with less elaborate mathematical apparatus. One is left with the feeling that considerable simplification may yet be effected in the presentation of these results, so that even a non-mathematical reader may be able to grasp the main issues. But, in the meantime, this small volume is likely to be of service to those seriously attacking the subject.

Vision and Colour Vision. By Dr. R. A. Houstoun. Pp. vii + 238. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1932.) 15*s*. net.

DURING the past twenty years, Dr. Houstoun has carried out many researches at Glasgow on the subject of vision and colour vision, and it is indeed fortunate, in these days when so much attention is given to the advertising value of a research subject, that so able a physicist is willing to work in a subject of such poor advertising value. Many physicists are too absorbed in the complexities of the atom to pay attention to the physics of vision and it would be of interest to know how many psychologists and physiologists are able to tackle the mathematics involved.

On reading this volume, which includes not only Dr. Houstoun's but also all other important work on the subject, one can well see that the author's devotion is due to the fascination of the phenomena. Studies of vision, like those of hearing, are much complicated by the power of adaptation of the organ of perception. The same result is not obtained when a red and a blue lamp are matched on a photometer bench close up to the photometer and afterwards at a great distance from it. Intensity discrimination, dark adaptation, acuity of vision, colour, flicker and fatigue phenomena all receive full treatment. After demonstrating the inadequacy of the Young-Helmholtz theory of colour vision, the author's own theory is proposed.

Evolutionist and Missionary, John Thomas Gulick: Portrayed through Documents and Discussions. By Addison Gulick. Pp. xvi + 556 + 3 plates. (Chicago: University of Chicago Press; London: Cambridge University Press, 1932.) 22*s*. net.

THE Rev. J. T. Gulick, who died in 1923, was an American missionary who will be remembered for his researches on the land-shells of the Sandwich Islands. He made a large collection, and observed that there were numerous species and varieties of each genus, which were restricted not merely to the same island, but even to the same valley. He thus elaborated a theory of divergent evolution by isolation, which he discussed in papers to the Linnean Society of London and in four letters to NATURE. On this subject he corresponded with A. R. Wallace, and especially with G. J. Romanes, who gave Gulick's work a prominent place in the third volume of his "Darwin, and after Darwin" (1897).

An interesting biography of Mr. Gulick, based on his letters and papers, has now been published by his son. One chapter is devoted to his correspondence with Romanes, and another gives a general summary of his scientific work, illustrated by three beautiful plates of the land-snails of the Hawaiian Islands.

Intermediate Physics. By Dr. C. J. Smith. Pp. viii + 650. (London: Edward Arnold and Co., 1932.) 14*s*. net.

FROM the point of view of science teaching, a physics textbook of intermediate standard is of great importance because for so many students it represents the end of their acquaintance with physics, the basic experimental science. The present volume is carefully written and is well illustrated with clear diagrams and references to the applied sciences. In view of the general teaching of calculus in schools, the author has not hesitated to use the notation and occasionally the methods of the calculus. At the end of each chapter is a good selection of numerical and other examples to be worked by the student.

The author has not ventured into the controversial and difficult problem of combining a little instruction in scientific method with the instruction in physics, and the book forms a good straightforward and conventional treatment perhaps specially suitable for the student likely to continue his physics beyond the intermediate stage.

The Medical Value of Psychoanalysis. By Dr. Franz Alexander. Pp. 247. (London: George Allen and Unwin, Ltd., 1932.) 10*s*. 6*d*. net.

DR. FRANZ ALEXANDER has dedicated his book on the "Medical Value of Psychoanalysis" to his master, Sigmund Freud, and it must be admitted that the pupil has proved worthy of the master.

It is very often a thankless and difficult task to convince medical readers of the value of psychoanalytical theories and practices. The author has, however, made out a very strong case for the development and improvement of medical education by the addition of courses in medical psychology, two courses being provided for undergraduates and one for graduates.

So many behaviour problems as well as what are obviously neurotic reactions are made to appear simple by the application of psychoanalytical technique to their investigation that the great value of psychoanalysis to medicine can no longer be denied.

Milne's Theory of the Expansion of the Universe

By DR. G. C. McVITTIE

PROF. E. A. MILNE has recently put forward in these columns[1] and also elsewhere[2] a theory designed to account for the phenomenon of the recession of the spiral nebulæ on purely kinematic grounds. The basic idea of this theory is both simple and elegant and can be described as follows.

Consider a swarm of particles moving with constant, but otherwise arbitrary, velocities in an infinite Euclidean space. The swarm has spherical symmetry around a point at which we can suppose an observer A to be stationed who employs a rectangular set of axes (x, y, z) and a Newtonian time t to describe the motions of the particles. Suppose that at $t = 0$ the swarm occupies the interior of a sphere S around A, who is at $x = 0$, $y = 0$, $z = 0$, the space outside S being empty. Then as time goes on, the particles will necessarily move out of S. For example, those near the surface of S having velocities directed away from A will immediately move out of S whilst others may have to traverse a portion, or the whole, of the sphere before they get outside it. But it is obvious that, given a sufficient lapse of time, the particles will sort themselves out so that eventually only the slowest moving ones will remain inside S. All the particles will, moreover, be now receding from A. If the original distribution of the velocities was continuous and included the velocity zero, there will always be some particles left *near* to A, and in fact it is not difficult to see that the average velocity of the particles at a distance r from A at time t is r/t, so that there is an approximate correlation of velocity with distance. Thus the behaviour of the swarm will be very similar to that of the spiral nebulæ observed in Nature, practically all of which are moving away from us with velocities which increase linearly with the distance.

The above result still holds when the distribution of particles is supposed to be infinite, provided only that there is an initial concentration of particles in the neighbourhood of A.

Milne now asks the question: What must be the space and velocity distribution of such a swarm so that a second observer, A', moving relatively to A with constant velocity and using a Euclidean space-frame (x', y', z') and a Newtonian time t', should have an equivalent view of the swarm? The principle of special relativity will ensure that the views of A and A' are consistent: to make them identical, Milne puts forward an extended principle of relativity, namely, "not only the laws of nature, but also the events occurring in nature must appear the same to all observers, wherever they be, provided their space-frames and time-scales are similarly oriented with respect to the events which are the subject of observation". These two principles are sufficient to enable him to determine, purely as a problem in statistics, the space and velocity distribution function of the swarm. It is, in terms of A's co-ordinates,

$$\psi\left(\frac{Z^2}{XY}\right)\frac{dx\,dy\,dz\,du\,dv\,dw}{c^6Y^{3/2}X^{3/2}} \tag{1}$$

where

$$X=t^2-(x^2+y^2+z^2)/c^2,\quad Y=1-(u^2+v^2+w^2)/c^2,$$
$$Z = t - (ux + vy + wz)/c^2.$$

This is the number of particles counted by an observer who sees the swarm centred around himself, in the volume-element x to $x + dx$, y to $y + dy$, z to $z + dz$, having velocities lying between u and $u + du$, v and $v + dv$, w and $w + dw$. All observers, of course, are supposed to be at the origin of their space-frames. The second observer A' will have an identical picture of the swarm if, and only if, his co-ordinate system is related to that of A by a Lorentz transformation of type

$$t'=\beta(t-Vx/c^2),\quad x'=\beta(x-Vt),\quad y'=y,\quad z'=z;$$
$$\beta=(1-V^2/c^2)^{-\frac{1}{2}}. \tag{2}$$

A' then sees the swarm centred around himself, and both A and A' count the same number of particles for equal volume-elements and equal velocity-intervals in their respective co-ordinate systems. Observers of this kind we call of 'class A'.

The condition that $x = 0, y = 0, z = 0, t = 0$ for A corresponds to $x' = 0, y' = 0, z' = 0, t' = 0$ for A' is necessary for the invariance of (1) under the transformation (2) and hence is necessary for the equivalence of the two pictures of the swarm. Consider now a third observer B who is *defined* as being at rest with respect to (say) A. He uses a co-ordinate system of type

$$t''=t,\quad x''=x+a,\quad y''=y,\quad z''=z, \tag{3}$$

where a is a constant giving the distance from A to B as measured by either of them. Milne recognises that B will not have an equivalent view of the swarm and attempts to overcome this difficulty by identifying B with an observer A'' of class A who is moving past B with velocity a/t at the instant t, having been at A at time $t = 0$. But it is not easy to see how this can be justified either on mathematical or on physical grounds. It would thus appear that Milne's extended principle of relativity is equivalent to a definition of a certain class of observers, namely, those who have equivalent views of the swarm of particles. These observers all coincided with one another and with the centre of the swarm 'simultaneously' and all set their clocks to read $t = 0$ when this happened. This moment can also be supposed to correspond to the moment of greatest concentration of the swarm and is so taken by Milne.

The distribution function

$$\frac{(\text{constant})\; dx\,dy\,dz\,du\,dv\,dw}{Y\left[c^2\sum(x-ut)^2-\sum\left\{v(z-wt)-w(y-vt)\right\}^2\right]^{3/2}} \tag{4}$$

has been specially studied by Milne: it arises from a particular solution* of his equation for ψ and corresponds to the case of rectilinear motions of the particles of the swarm as viewed by an observer of class A. This is therefore the case when the interactions of the particles are neglected. It follows that at $t = 0$ there were an infinite number of particles at the origin. At any subsequent $t > 0$, particles which were initially at the origin and moving with velocity V, will have got to $r = Vt$ and evidently these particles again have an infinity in their distribution at that distance. Thus these infinities recede from the observer with velocities proportional to their distances from him. The general effect of gravitation is to remove these infinities and to replace them by density-maxima in the distribution of the particles. Thus finally we have a set of groups of the original particles which appear to any observer of class A to recede from him according to the law $r = Vt$. However, there still remain singularities in the distribution of the groups on the sphere $r = ct$, so that the latter are strongly concentrated there. Milne identifies the groups with the spiral nebulæ, thus obtaining the law of velocity of recession proportional to distance. The concentration towards $r = ct$ is shown to be consistent with the apparent uniform distribution of the nebulæ owing to the rapid diminution of brightness due to the high velocity an object acquires on approaching this bounding sphere.

From the observed correlation of 500 km. per sec. for every 3·25 million light years distance of a nebula and the law $r = Vt$, it follows that $t = 2 \times 10^9$ years have elapsed since the system of the nebulæ was at its greatest concentration.

We may in conclusion contrast Milne's theory with that based on general relativity. The latter deals only with the group of observers at rest with respect to one another, who are observing a set of particles also at rest with respect to the observers in the sense that the total momentum of the particles is assumed to be zero. The particles initially are in a state of unstable equilibrium and the expansion is due to what may be called a 'cosmical repulsion'. In Milne's theory the particles are initially in motion and are not in an equilibrium state. The observers considered are not at rest with respect to each other. The expansion is simply due to the fact that the particles in a certain region have higher velocities on the whole than those elsewhere. Both theories are in accordance with observation and it seems impossible to decide definitely for or against either so long as the phenomenon of the recession of the nebulæ, in isolation from all other phenomena, is to be the only criterion.

---

* It appears as the *only* solution in the paper quoted in (2). Prof. Milne has since discovered others.

Nitrogen-Uptake of Plants

PROGRESS, due to the abandonment of traditional beliefs, is occurring to-day in agriculture as well as in other branches of applied science. At one time it was generally held that ammoniacal nitrogen had first to be converted into nitric nitrogen before it could be taken up by plants, but we now know of many plants that take up ammoniacal nitrogen directly; and at the present time doubt is being cast on a doctrine which has persisted since the days of Liebig and Boussingault, namely, that organic nitrogen has first to be 'mineralised' before it becomes available as food for plants. The work done by Prof. A. I. Virtanen and his collaborators at Helsingfors during the past few years has provided important evidence that at least some plants directly and readily assimilate organic nitrogenous compounds, and a useful summary of this work was given recently by Prof. Virtanen in lectures delivered to the Netherlands Agricultural Society at Wageningen and to the Chemical Society of Zurich.

Earlier experiments showed that certain legumes, for example, red clover, did not grow so well when the nitrogenous food derived from the root nodules was replaced entirely by ammonium nitrate, but that peas utilised both forms of nitrogen equally well, whilst white clover responded better to ammonium nitrate than to the food provided by the nodule bacteria. These and other observations led to the hypothesis that legumes take up their nitrogen from the nodules in the form of organic compounds, and that these compounds constitute the best form of nitrogen-nutrition for certain legumes. It was also found that these compounds diffuse into the surrounding soil, from which they are taken up by growing plants, like *Gramineæ*. Both pot and field experiments have shown that, when the pH of the soil does not fall below 6, one pea plant can provide sufficient nitrogen for two oat plants, but if the ratio of oats to peas is greater than two to one, both plants suffer from lack of nourishment.

Investigations were then made using sterilised sand and pea seeds inoculated with nodule bacteria, and it was found that the nitrogenous matter that diffused into the sand consisted entirely of organic compounds, which were almost equal in amount to the nitrogen compounds directly taken up from the nodules. It was also established that nitrogen compounds diffuse into the soil from young and fresh root nodules of the alder tree, thereby enabling the latter to assist the growth of other trees.

Analysis of the substances that diffused into sterile quartz sand from the roots of pea plants that had been strongly inoculated showed the chief constituent to be amino-acids: in percentages of total nitrogen, amino-nitrogen 77·4, ammonia-nitrogen 0, amido-nitrogen 3·30, nitrogen in volatile bases 2·73, humin-nitrogen 2·05.

The question then arose whether non-legumes could take up and utilise these nitrogen compounds directly, and to solve it pea and barley plants were grown together in sterile sand contained in three-necked Woulff bottles, the pea seeds being inoculated, and each kind of plant being made to grow out through a neck of the bottle. The nutrient solution used contained no nitrogen. The barley plants grew excellently, but in the control experiment, in which the pea seed was not inoculated, they failed to grow. It was also found that barley, as well as peas, grew exceedingly well right up to the flowering or fruiting stage when they were fed with an aqueous extract of a low moorland soil that contained no ammonia or nitric nitrogen; they also grew well when they were fed in sterile culture with peptone (Witte) as their sole source of nitrogen. It is therefore concluded that higher plants can take up and utilise directly organic nitrogen compounds present in soils before their nitrogen is mineralised by bacteria or other micro-organisms.

The nature of the organic nitrogenous compounds that are of value to plants, as well as their percentage utilisation, is now being investigated. Earlier experiments in which red and white clovers were grown under sterile conditions inside glass flasks showed that red clover responded well to hydrolysed casein and to aspartic acid, and less well to ammonium salts and nitrate, whereas with white clover the results were exactly opposite. In these experiments the hydrogen ion concentration of the nutrient solutions containing hydrolysed casein and aspartic acid remained constant, showing that the nutritional effects were due to the amino-acids themselves and not to ammonia that might be liberated by their decomposition. The later experiments, in which the plants were grown with their roots in sterilised nutrient solution or sand and their upper parts in the air, have shown that aspartic acid is a very good nutrient for legumes, but not for *Gramineæ*, and that asparagin is excellent for barley, but much less good for *Leguminosæ*.

The manner in which the plants utilise such organic compounds can at present only be conjectured. On one hand, it may be that enzymes like urease, asparaginase or aspartase liberate ammonia from these organic compounds when they are still in the root system, and that the plants utilise this ammonia to synthesise protein. On the other hand, it is also possible that the amino-acids may be utilised directly for the synthesis of protein.

Enzymes: A Discovery and its Consequences

By Dr. E. F. Armstrong, F.R.S.

It is a hundred years since Payen and Persoz discovered diastase and recognised it as a ferment. To-day the ferments, or enzymes as we have preferred to call them, are in the forefront of interest as the factors concerned in all those chemical changes in the cell which in their totality are termed vital changes: they may indeed compose those invisible genes which make up the chromosomes. The discovery of diastase, apart from its broader consequences, has had a far-reaching effect also in introducing science into one of the oldest industries, one already established on the Nile in the days of the Egyptians, that of brewing: the determination of diastatic power is to-day one of the first exercises which is performed on the new season's crop of barley and malt. The studies on diastase made in the cause of brewing have in turn enriched chemical science, and there is a notable list of eminent brewers' chemists to inscribe on the roll of honour of enzyme pioneers.

The discovery of Payen and Persoz in 1833 followed an observation by Kirchhoff that germinating barley grains contained a principle capable of converting starch into sugar, a power which Leuchs discovered was also possessed by human saliva. Payen and Persoz found out how to extract ground germinating barley with water and, after filtration, precipitate a white flocculent material by means of alcohol, which when dried and redissolved turned starch into sugar. Their procedure was that which is followed to-day in extracting an enzyme, though our hands have gained not a little cunning in concentrating the enzyme and freeing it from this and that impurity, largely as the result of methods devised and elaborated by Richard Willstätter, who was Davy medallist of the Royal Society in 1932. The active material was named 'diastase' by its discoverers. It was found by them to be present in other cereals during germination, and during the 'seventies, numerous workers established that diastase is very generally present in vegetable cells so long as the latter are living. In the meantime, Miahle had made a diastase by adding alcohol to saliva, and other observers found it in the animal pancreas. Animal diastase is generally referred to as ptyalin in the literature and in many textbooks the term amylase is preferred to diastase; a proper sense of historical loyalty should, however, make us adhere to the older term.

In any mention of the diastase story, the work of Horace Brown and Morris in connexion with the translocation of starch comes immediately to mind. The formation of diastase in foliage leaves during darkness and its conspicuous diminution during bright sunshine, were discovered by them and used to explain the behaviour of starch, which varies in amount in the opposite sense during the twenty-four hours. Classical also are the studies of Cornelius O'Sullivan at Burton-on-Trent of the action of malt diastase on starch, published in 1876: they mark a beginning of the efforts to establish the kinetics of enzyme reactions and also to unravel the structure of starch itself.

We are still working at this problem—starch—nearly sixty years later, without any certainty that the goal is in sight, though the work of Haworth is definitely carrying us forward: it is successful perhaps because he is taking nothing for granted and is insisting on the need of relying only on the evidence furnished by quantitative laboratory work. The newer branches of chemistry, X-ray analysis and colloid conceptions, have been called in to help establish the size and form of the starch molecule, but the results obtained with their aid are definitely of a more speculative character.

Many have toiled, others may be said to have toyed, with the kinetics of enzyme action, but the chief result has been to introduce confusion into what at bottom is simple, once the disturbing factors have been eliminated. We would rather write of diastase in relation to starch from the point of view that the enzyme itself must be a composite material. The evidence is becoming more precise that the maltose units in starch are not all joined together in the same manner and that there are perhaps two different and separable diastases, which act differently upon starch, one producing the α-form of maltose, the other the β-form.

Starch is the largest item in our dietary, it is the most common reserve material of plants, in the industrial arts it has a thousand and one uses, it is the basis of beer, its study forms the most intriguing chapter of vital chemistry. Is it not remarkable that there is still more that is obscure than is definite in our knowledge of the structure of its molecule and its microscopic and macroscopic make-up?

Following the discovery of diastase, other enzymes attacking substances other than starch have been found in both plants and animals. Studying the behaviour of first one and then another of these, it has become possible to establish their general properties, in particular their high degree of specificity, the ease with which their activity is destroyed or modified by chemical or physical alteration. They have very many properties of the living unit, except the all-essential one—they are incapable of self-duplication. The enzyme particles are non-resolvable under the microscope. Jerome Alexander has emphasised their resemb'ance to the self-reproducing ultramicroscopic genes of which the chromosomes are thought to contain immense numbers, and there are adherents for the idea that the genes may be regarded as enzyme-like catalysts, capable of self-duplication, which dominate by their catalytic control of chemical changes what is to happen in their neighbourhood. They are capable both of self-duplication and of initiating and controlling each and every chemical reaction in the cell, the only proviso being that the necessary raw materials for the catalysed reactions are provided in the milieu and that the supply of the raw materials and the removal of the products of metabolism proceed at suitable rates of speed. Each gene may be supposed to catalyse one reaction only and its catalyst to be composed of a single molecule; in practice, there will always be large groups or strings of genes. Our methods of isolating and purifying or concentrating enzymes, after the breakdown and killing of the cell, aim at the selection of the catalyst derived from a single gene: it will be obvious how Utopian this quest must be.

The great majority of enzymes act, like diastase, as catalysts of hydrolysis; that is to say, the elements of water enter into the reaction, which indeed commonly takes place in the presence of an excess of water. The amount of water in the cell, its relative abundance in a free and active state, unattached to or uncombined with other substances, is an extremely important, if not the determining, factor in governing the direction and position of the final equilibrium, for it is in the highest degree probable that the same catalyst which favours hydrolysis can also, under other conditions, accelerate the reverse change, that of synthesis. The factors which control the activity of a cell are the catalyst, a supply of raw materials and the presence of more or less active water. When there is excess of water the reactions are those of hydrolysis; when there is a scarcity of water and the cell sap is concentrated or saturated, which is another way of expressing that the water molecules are all occupied, the reactions are those of synthesis.

There is now a consensus of opinion that enzymes consist largely of organic matter made up of at least two units, the carrier, forming a large colloid particle, and the other, the active substance, which is held or oriented in an efficient position and stabilised by the carrier. Without the carrier the catalyst cannot function, and consequently, when the process of purification leads to a disruption of the carrier, the catalyst loses its activity. Such a statement is to some extent incompatible with the possibility of isolating a definite crystalline enzyme, as Northrup claims to have done for pepsin and trypsin; more enlightenment is obviously required on this point before a final opinion can be pronounced.

The enzyme study began with Payen and Persoz; its first century of endeavour may be said to have ended with the anniversary address of Sir Frederick Gowland Hopkins to the Royal Society last November, wherein he summarises the present conception of an enzyme and emphasises the importance of the conviction which is now general amongst biologists that modern chemical methods, starting with isolated reactions made with tissue extracts and passing to studies of other tissue extracts in which the progress of a variety of reactions is studied, do in fact give a picture of the reactions which are taking place in intact or still living tissues or cells. In his words, we have escaped from the dilemma voiced in earlier dogma, that since chemical methods convert the living into the dead, they can do nothing to elucidate the dynamic events of life.

Such is the progress of the century. Since the discovery of the first enzyme we have travelled far to form a conception of an enzyme as an active spot of specific configuration at part of the surface of the colloid particle. Progress has been slow, largely because chemists and biologists have not been ready for such a conception and all that its application involves. Now at the beginning of the second century of enzyme study, things are different; the authoritative summary by the president of the Royal Society in closing the old period serves to open the new at a moment when the army of research workers is ready to apply it.

Obituary

PROF. C. CORRENS

THE death on February 15 of Prof. Carl Correns at the age of sixty-eight years leaves a gap in the ranks of those who were prominent in the Mendelian investigations from their inception in 1900. Much of his work was in the more obscure and difficult fields of plant genetics, such as self-sterility, variegation and the inheritance of sex. He brought a wide knowledge of plants and a broad biological outlook to bear on these and other problems, and will always be held in remembrance as one of the three co-discoverers of Mendel's principle of segregation in hybrids.

When Hugo de Vries published his paper "Sur la loi de disjunction des hybrides" in the *Comptes rendus* of the Paris Academy of Sciences in March 1900, announcing the re-discovery of Mendelism, based on the study of eleven different species, Correns was stimulated to write immediately, as he says, a paper for the *Berichte der deutschen botanischen Gesellschaft*, which was entitled "G. Mendel's Regel über das Verhalten der Nachkommenschaft der Rassenbastarde", in which he showed how he had independently arrived at the same conclusions as de Vries through experiments with maize and peas. He, like de Vries, at first thought his results and conclusions were new, and then found Mendel's paper of 1866 with similar results and the same explanation of them, namely, the principle of genetic segregation. In the previous year he had published an explanation of the phenomena of xenia in maize and in 1901 he wrote another extensive and classical paper on this subject.

Correns was thus a leading spirit in the rediscovery of Mendel's laws and in a clear statement of the mode of sex determinations in diœcious and polygamous flowering plants. Important investigations on the latter subject were published in 1907, in which the Mendelian conceptions were applied to the inheritance and determination of sex in plants. This was the period when active discoveries of the sex chromosomes in insects were taking place, and in 1913 he published in collaboration with Goldschmidt a general work on what we would now call the genetics of sex. Several other investigations of sex in plants appeared during the next decade, *Melandrium, Silene* and *Rumex* being among the forms mainly studied.

Many of Correns's researches were fundamental and he preferred to labour in fields that were off the beaten track. The number of plant genera with which he worked at different periods was a surprisingly large one. In a series of papers on *Mirabilis* hybrids, beginning in 1902, he showed that when the yellow and white varieties are crossed, the F_1 is rose-coloured with red stripes while the F_2 produces no less than eleven colour types. This was important at a time when it seemed that Mendel's law of dominance might be as fundamental as his law of segregation. The influence on the offspring of the number of pollen grains placed on the stigma was also investigated in *Mirabilis*, and several interspecific hybrids of *Matthiola incana, M. glabra* and other species were analysed. Other genera the genetics of which he studied included *Urtica, Trinia, Hyoscyamus, Dimorphotheca, Lamium, Veronica* (long and short style), *Linum* and *Fagopyrum*.

Correns was interested in the rôle of the cytoplasm in inheritance and published an important paper on this subject in 1909. He studied variegation and its inheritance, finding cases where the development of the chloroplasts was under nuclear control and therefore Mendelian in inheritance, while in other cases the control was cytoplasmic. His paper at the Berlin Congress of Genetics in 1927, of which he was a vice-president, was a masterly summary of knowledge regarding non-Mendelian inheritance in plants and animals, but he was prevented by illness from giving it in person.

So early as 1889, Correns made a study of pollen germination and the pollen tubes of *Primula acaulis*, and much later he showed in *Melandrium*, by placing a few pollen grains on the stigma, that the upper ovules of the flower are generally fertilised first.

Darwin's experiments on self-sterility led him to the view that in such cases each plant, although self-sterile, can be fertilised by pollen from any other plant. This hypothesis of individual stuffs was held until the work of Correns on *Cardamine pratensis* in 1912, in which he found that the offspring of two crossed plants fell into four interfertile groups, and the inheritance of self-sterility could be explained on a Mendelian basis. This conception has since been confirmed and extended in other genera. In 1928, however, Correns found that in *Tolmiea Menziesii* the individuals from a cross were fully fertile with each other, as Darwin had supposed, and it is possible that in this species the determination of the stuffs inhibiting pollen tube growth is not genotypic but phenotypic.

Correns was born in Munich on September 19, 1864, his father being a painter and a member of the Bavarian Academy of Art. In 1892 he went to Tübingen and in 1899 was made an extraordinary professor in that University. He went from there to Leipzig in 1902, and in 1909 became professor of botany at Münster in Westphalia. It was there that I first met him, in 1910. An animated discussion with him in the streets of Münster, surrounded by curious onlookers, made one feel rather like one of the disputants in a university town in the Middle Ages. With his bright red hair, thick glasses and large hands with extremely long nails trimmed to a point, he was a man of extraordinary appearance in his younger days. When the Kaiser Wilhelm Institute for Biological Research was founded at Berlin in 1914 he was called to be its first director and was also made an honorary professor in the University of Berlin. His connexion with this research institute was maintained to the end, its extensive garden, greenhouses and laboratories being the scene of all his later work. An early work, published in 1899, had to do with vegetative multiplication in the mosses, but nearly all his later investigations had some bearing on genetics.

In 1924, on the occasion of his sixtieth birthday, Correns's collected works on plant genetics, numbering sixty papers, were published in a volume of some 1,300 pages. He married a niece of Nägeli and published (1905) Mendel's letters to Nägeli, in which an unsuccessful attempt was made by Mendel to interest Nägeli in his views regarding the phenomena of heredity. They were republished as an appendix to the volume of collected works.

Correns may be said to occupy a somewhat similar place in modern plant genetics to that of Kölreuter in the eighteenth century. His results were always clearly and methodically presented. He held several honorary degrees, was a member of the Prussian Academy of Sciences, and in 1931 was elected a foreign member of the Linnean Society of London. R. RUGGLES GATES.

WE regret to announce the following deaths:

Prof. C. W. Cook, professor of economic geology in the University of Michigan, known for his work on oil geology, on February 17, aged fifty years.

Prof. Erik G. Odelstierna, professor of the metallurgy of iron in the Technical High School, Stockholm, from 1904 until 1918, aged seventy-nine years.

News and Views

Education and Economic Recovery

IN his chancellor's address to the University of New Zealand, Dr. J. Macmillan Brown emphasised the contribution of education to recovery from the periodic economic and financial depressions in the assistance it gives to the growing mind to understand the methods and efforts of the past. Youth must be trained to know the data of the situation before it is stirred to investigate and learn the full terms of the problem before attempting its solution. Accordingly, education, and especially advanced education, should be the last element in a civilised community to be submitted to the axe of economy in meeting the want and suffering associated with a depression, and the pruning of educational resources in New Zealand and elsewhere is a definite setback to recovery. The two essentials in the recovery of a community from depression are the broadening and deepening of the intelligence of the mass so as to enable them to learn the lesson of thrift and foresight, and highly developed leaders capable of seeing far into the darkness of the future and leading their fellows to the highest practical goal. The selection and training of the intellectual leaders is the more important for advance in research, and a large proportion of exceptional material is left undeveloped in the absence of scholarships to select and carry it through its course.

IT is the true function of a university, Dr. Macmillan Brown said, to select the research workers and leaders of thought who will save mankind from these recurrent dilemmas. Universities and institutions which prepare for them are the main means by which the methods of one generation are stored up and improved for the benefit of subsequent generations. Dr. Macmillan Brown pointed out that more and more widely is it being realised that self-isolation of the individual, the caste, the community, and the nation is suicidal,and destructive of progress, and he urged that the transmission of advance from one community and one generation to others can only be effective, beyond such institutions as the British Commonwealth of Nations and the League of Nations, if there is fellowship and effective international co-operation between the universities. With the universities and their graduates forming the constituencies in every nation and community, mankind might make some approach to a world parliament or at least to a conference which would be competent to indicate sanely the conditions that should belong to a federation of the world. Dr. Macmillan Brown concluded his plea for the place of a trained intelligence in the direction of the affairs of mankind by pointing out that university education must be built on broader foundations than narrow specialisation and be capable of selecting the wisest, most developed minds and characters the community can produce.

Roman Richborough

AFTER eleven years excavation on the site of Roman Richborough, it is at last possible, according to the account of the most recent discovered given by

Dr. J. P. Bushe-Fox before the Society of Antiquaries on April 6, to assign a purpose to the large timbered buildings occupied during the first half century of the Roman conquest of Britain. It is now evident that these buildings, differing in character from both barracks and structures for domestic occupation, were port store-houses for grain and other material. The outlines of rotted beams, piles and foundation trenches, indicate that they were erected in rectangular blocks or *insulæ*, each comprising four buildings. Of these, one faced the main road and the other three lay behind, with approaches from the side roads which bounded the *insulæ*. Each building was provided with a loading platform, while that facing the road had also a space in front in which carts might draw up. This building was erected on a massive beam platform, embedded in the soil, to take heavy weights; but the remaining three were erected on piles to give the ventilation necessary to protect corn against the effects of damp. No other granaries such as these are known. Another building, also unique in character, lies on the other side of the road. It is a rectangular structure erected around a court. Each side consists of two rows of rooms, ranged in pairs. It is conjectured that these were the quarters of the police guarding the stores. Dr. Bushe-Fox describes the whole base camp as an unprecedented discovery. His account of the arrangements for unloading and storing material had an almost disconcertingly modern note.

Completion of the Grid in Great Britain

THE fifth annual report of the Central Electricity Board, which has just been published, is of special interest as it is the last of the reports marking the construction of the grid in Great Britain. It has only taken six years to complete instead of the estimated eight years. The cost is less than 27 million pounds and is within 2½ per cent of the original estimate of the Electricity Commissioners, a very satisfactory result considering the work has been so accelerated. In future, the main business of the Central Board will be in connexion with grid trading. The main function of the grid is to see that there is an abundant supply of electrical energy at each central station so that the engineers will have more time to devote to the increase of their sales. The report shows that continuous expansion is taking place in outlying areas supplied by secondary transmission lines. The Weir Committee thought that it would be best that most of the secondary transmission should be carried out by the distributing authorities, but the Central Board found it best to regard these lines as part of the grid and so help the distributors. Successful researches have been made on methods of cheapening the cost of tapping the grid. This is a step towards supplying sparsely populated districts with electric light and power and thus encourages rural development. Instead of a tapping costing £20,000, it is hoped to reduce it to £4,000. It was feared at one time that difficulty would be obtained in getting wayleaves, but out of twenty-one thousand wayleaves obtained, less than six hundred (2·83 per cent) had to be acquired compulsorily.

The French Grid

THE new electric transmission line which has just been opened between the Massif Central and Paris will greatly facilitate the supply of electrical energy in France. The station on the River Truyère, a tributary of the Garonne, is one of the largest and finest hydro-electric stations in Europe. We learn from the *Electrician* of March 24 that the pressure is 220 kilovolts; this compares with 132 k.v., the pressure used on the British grid. The line starts from Rueynes, passes by Marèges, Eguzon and Chagny and ends at Chevilly, which is south of Paris. At present, the line can carry 100,000 kw. When the new Sarrians station is completed in a few months' time, the power transmitted will be doubled by means of a second line which is under construction. The first part of the 220 k.v. line was constructed by the Paris-Orleans Railway in order to safeguard its supply for traction purposes. It was first operated at 150 k.v., but this was modified a year ago by the addition of supplementary insulators to the strings of insulators then in use. This enables it to work at 220 k.v. Luckily, the three overhead conductors had been placed 7·8 metres apart initially, so the conversion was easily effected. The average span between the lattice towers is 250 metres and the lines are of steel-cored aluminium. The distributing stations for the Paris region are supplied by three underground lines with energy at 60,000 volts. Provision has been made so that five more of these lines can be laid when required. The important falls of the Massif Central are now connected with Paris. The joining up of the stations at the falls in the Alps and on the Rhine with the falls of the Massif Central is a most satisfactory engineering achievement.

Sir Ambrose Fleming on Television

THE fourth Exhibition of Television and Photo-Electric Apparatus was opened at the Imperial College of Science, London, S.W.7, by Sir Ambrose Fleming on April 5. In the course of his remarks, Sir Ambrose said that the invention of television has gone through the usual three stages. First, when everyone thought it could not be done at all. Second, when leading experts declared that even if it could be done, it was no possible use, and third, when the wiseacres said, we knew it could be done, but it is not a commercial proposition. "It has been my good fortune to be closely and practically connected with the introduction into great Britain of three important inventions, namely, the telephone, the incandescent electric lamp and wireless telegraphy, and I have seen these three stages illustrated in them all. Television by Baird's system is now a practical achievement and capable of being of real entertainment value, as those know who have seen the nightly demonstrations of it by a good receiver. Our great grievance at present is the impossible hour at which the B.B.C. broadcast it, namely, 11-11.30 p.m." There is need for a careful scientific study of the subjects that can be 'televised'. Television is a new art and has new principles connected with it. The substantial facts on which it is based are well known and the keen amateur is doing not a little to push it forward. This exhibition showed how much has been done in this respect, and also how much is being done by great corporations with large resources.

IT is, however, necessary that the ideas of the public on television should not be turned in the wrong direction by exaggerated or imaginary statements as to its real and possible achievements, because then only disappointment results when the true facts are known. "We cannot yet televise directly a cricket match at Lords or a Cup football contest at the Crystal Palace. But what we can do is to take on a moving film with a camera certain not very quickly moving objects of large size and televise this film. There is an immense field in this respect for educational work. The Latin poet Horace told us, what every advertiser knows well, namely, that memory of the eye is more tenacious than memory through the ear. We can televise geometrical diagrams, lessons in botany, physics, and zoology, and countless other useful visions. Let us hope that this new weapon science has provided will not be vulgarised or put to base uses, but employed for the instruction, elevation and national entertainment of the public at large."

Eugenics and Marriage Laws

IN a note contributed to the *Bulletin of Hygiene* for February, Lettin M. Crump discusses the introduction of pre-marital health certificates from the point of view of eugenics. In Mexico, impediments to marriage include insanity, and similar restrictions extending to imbecility or feeblemindedness are found in certain of the United States. The growing practice of requiring a certificate from a qualified medical practitioner for insurance purposes, as well as from candidates for public appointments, seems likely to undermine opposition on this score, and with a more enlightened public opinion the need for compulsion would be greatly lessened. In some countries, notably Austria, Germany and some of the United States, the establishment of centres for giving advice on all matters concerning marriage has found favour. Useful advice can only be given when the investigator has a knowledge of the applicant's physical and mental condition as well as of his hereditary background and that of his proposed partner, the type of inheritance of any heritable disease or defect which may be present in the pedigree and of the effect which other causes may have upon the appearance of such heritable conditions. Mendelism provides us with a growing body of available information concerning inheritance in man, and evidence collected in the working of marriage advice bureaux leads to the conclusion that feeblemindedness is in many cases inherited and usually behaves as a recessive; the mating of possible heterozygotes is undoubtedly to be discouraged. Although evidence collected from pedigrees is frequently both vague and faulty, justice demands that every available means of making public such information as exists should be fully used so as to enable the conscientious citizen to avoid handing on defects from generation to generation.

Anthropological Teaching and Research in Australia

THE passing of a resolution by the Australian and New Zealand Association for the Advancement of Science at its meeting at Sydney in August last, urging upon the Government the need for anthropological training for all white people who hold positions of authority or control over natives, has moved Prof. Raymond Firth to open the new volume of *Oceania* (vol. 3, pt. 1) with a survey of the progress of anthropology in Australia in the period 1926–32. The choice of this period as the limit of his survey is determined by the fact that its beginning coincides with the setting up of a Department of Anthropology in the University of Sydney and the appointment of Prof. A. Radcliffe-Brown to the chair, as the result of a resolution passed at the Australian meeting of the Pan-Pacific Congress in 1923. At the same time, a comprehensive scheme of research was initiated under the direction of the Committee for Anthropological Research of the Australian National Research Council, for which funds have been generously provided by the Rockefeller Foundation. In what has been accomplished, much has been due to Prof. Radcliffe-Brown, who, in virtue of his position in the University of Sydney and on the Research Council, has acted as a link in bringing closely together teaching and research. Investigation has been directed to both human biology and social anthropology. Not only has the work of Spencer and Gillen in central and northern Australia been continued and extended, but Prof. Radcliffe-Brown and others have also conducted investigations in areas in the east and the west of the continent. In looking forward, Prof. Firth sees that much virgin soil has to be explored, not only in Australia, but also in New Guinea and Melanesia; but in the first-named, he points out, there is need for haste lest the material vanish.

Racial Distributions in Palæolithic Europe

IN some 'notes' contributed to the *Proceedings of the Prehistoric Society of East Anglia* (vol. 7, pt. 1) Mr. M. C. Burkitt offers some interesting suggestions as to the possibly dual origin of the races and cultures of palæolithic age in Europe. He points out that it is no longer possible to accept the unfailing regularity of the sequence of cultures as originally classified by the French archæologists, and points to the contemporary existence, as proved by the fossil fauna, of a core industry, the *coup de poing* of Chelleo-Acheulean times, on the west bank of the Rhine and of flake industries on the east bank, the two intermingling on the border line in eastern France, in southern Belgium and in Britain as seen in the Levallois and Clactonian industries. He goes on to point out that, while the *coup de poing* does not occur east of the Rhine with a few exceptions, the flake industry can be traced, except for certain gaps, from east of the Rhine right across Europe and Asia to China, where perhaps it finds its prototype in the flake implements of Peking man. This, to his mind, suggests a dual origin for the races of early palæolithic Europe, one branch coming from Africa where the *coup de poing* occurs with some frequency, and the second bringing the flake industry from Asia. He applies the same argument to Aurignacian man, pointing out that while the female statuette of upper palæolithic date has never been found in Africa, it occurs in Russia and examples have recently been found so far east as Maltá in Siberia. As the African affinities of Aurignacian man, or rather of his culture are not to be questioned, Europe would again in this period represent the point of confluence of two streams of migration.

Prof. A. Stoll's Researches in Biochemistry

THE biochemists in Germany publish their results in the *Biochemische Zeitschrift*, and some ten thousand original papers have been published in it in the past twenty-six years. The American and British work has been even more fruitful, at least in quality, during this period, so that there is little wonder that we are beginning to make progress in unravelling both the nature and structure of the substances found in the living cell and in understanding something of the reactions which take place there. Prof. Arthur Stoll of Basel has recently put together, for the purpose of a lecture, his own experiences since 1909 in developing some sections of biochemistry ("Ein Gang durch biochemische Forschungsarbeiten", pp. 41+5 plates. Berlin: Julius Springer, 1933. 3 gold marks), much as in another walk of life a traveller might do on his return from a lengthy journey. Stoll began research with Willstätter and the chlorophyll molecule, and he returns to it at the end of his journey, for it has not yet given up all its secrets. In the meantime he has concerned himself with ergot, with scillarin, and with the digitalis glycosides. His pamphlet, which is illustrated, makes attractive reading: we concern ourselves too much nowadays with the abstruse intricacies of our sciences, and would be well advised to view them occasionally from a wider angle.

Reopening Limestone Oil Wells with Acid

THE natural flow of an oil well may recede either from the exhaustion of the oil supply or as the result of a stoppage of the pores of the oil-bearing rock cutting off the free supply of oil. In the past, somewhat drastic methods have been tried to overcome this drawback, but they are difficult to carry out, especially at a depth which may be half a mile below the surface. When the well is in a limestone formation, it has now been discovered that it is possible to open it up again by treatment with successive quantities of 10 or 15 per cent hydrochloric acid, which dissolve new channels in the calcareous rock and permit of a new flow of oil. The use of hydrochloric acid is only made possible by the addition to it of 1–5 per cent of an arsenic compound, which inhibits the action of the acid on the metallic casing and pump tubes of the well. Other inhibitors, including certain organic nitrogen bases, have been discovered but the arsenic compounds are the most convenient to apply in practice. The discovery has been made by the Dow Chemical Co. in partnership with the Pure Oil Co., and patented as the Dowell process: it is described in greater detail in the News Edition of *Industrial and Engineering Chemistry* for February 20. The use of acid made inactive towards metal surfaces is a novel and important one: it may be a revolutionary factor in oil production. Further, it is likely to be beneficial in natural gas production and in other directions. It is certainly an achievement to be able to control the action of a strong acid as a boring agent half a mile below the surface.

Petroleum Production in Russia

ACCORDING to Science Service of Washington, D.C., the petroleum production of Soviet Russia has now attained the position of being the second largest in the world, the estimated yield last year being 150 million barrels. Many factors have conduced to this remarkable advance, but chiefly the confiscation of oil property and its operation under Government directorship without competition have been responsible. The fields have the additional advantage that they are well situated for transport of oil to foreign markets and they are also easy to develop and operate. Another factor in the situation is the results of exploratory work, which have indicated the existence of potential oilfields along a tract of country stretching from the Arctic Ocean to the Caspian Sea. From the point of view of economics, as emphasised by Mr. R. C. Beckstrom to the American Institute of Mining and Metallurgical Engineers recently, Russia's home consumption is based mainly on industrial development and particularly on the extensive use of tractors for agricultural purposes, while external markets for oil lie chiefly with Italy, France and England, to which more than forty million barrels were exported last year. If the ambitious goal of more than 480 million barrels of oil production for 1937 is realised by the Soviet authorities, then clearly the whole scheme of international stability, in so far as petroleum supplies are concerned, will receive a severe shock.

Institution of Heating and Ventilating Engineers

THE Institution of Heating and Ventilating Engineers of 12, Russell Square, W.C.1, now issues a *Journal*, the first number of which was published in March. The object of the *Journal* is to keep its members in touch with the latest practice both at home and abroad and in particular to give them the latest results of the research work being done on the subject. In the first issue, an important paper by E. Herring is published giving the methods that have been employed for warming and ventilating the Masonic Peace Memorial building in Great Queen Street, London, W.C.2. As many masonic meetings will be held there, it was necessary to use special precautions so as to eliminate the possibility of sound being transmitted from one room to another. All the fans, motors, and machinery had to run silently and it was necessary that the rate of ventilation and the temperature of each room should be controlled from the engineer's room, so as to obviate the necessity of the engineering staff having to enter any 'lodge' room. The 'lodge' rooms are designed to give a maximum supply of conditioned fresh air equivalent to 1,750 cub. ft. a head an hour. A refrigerating plant is installed for cooling and removing the moisture from the air when necessary. In winter, hot water is supplied by steam-heated storage calorifiers but in summer, owing to the small demand, an electrical thermal storage system is employed. Steam for all purposes is generated by four steam boilers working at a pressure of 100 lb. per sq. in. and capable of evaporating 7,000 lb. of water an hour at 212° F. Storage for the oil fuel is provided by five cylinders having an aggregate capacity of sixty tons.

Research at the Dove Marine Laboratory, Cullercoats

THE Report of the Dove Marine Laboratory, Cullercoats, Northumberland, for the year ending June 30, 1932, has recently been published. The research during the year dealt chiefly with herring investigations, work on pollution, conditioned responses in fishes and hydrographical records. Large numbers of young herrings with three winter rings were present in the East Anglian October shoals. A new year class, that of 1928, has appeared in the winter shoals about the north of Scotland. It was not present in the samples from north-west Ireland. Mr. Storrow's work includes notes on organisms coming with the Atlantic waters during the last few years, the abnormal flow in all probability influencing the herring fishery, especially in the Clyde. His conclusions from the age composition of the Northumberland herring shoals are that the data support the idea of a gradual change in the fishing rather than change due to recent oceanic activity. Prof. Meek's work, with the help of Miss Benton, on *Sagitta*, shows that *Sagitta setosa* may be an important indicator of currents. Dr. Bull's researches on fish behaviour have been helped greatly by the erection of a partially sound-insulated and entirely separate building. Conditioning experiments involving the stimulus of small temperature increments and changes of direction of current flow are in progress and positive results have been obtained. In his work on the study of colour vision by the technique of differential inhibition, Dr. Bull has shown that the common shanny, *Blennius pholis*, has a wide range in wave-length discrimination, being able to distinguish one colour from another in many instances.

Coco-nut Palm Products

COCO-NUT oil derived from copra is by far the most important ultimate product of the coco-nut palm, and the future prospects of the industry are reviewed in a volume under this title, which appears as the second volume of a "Survey of Oil Seeds and Vegetable Oils" (London: H.M. Stationery Office, 2*s.* net). Within the last ten years there has been an increase of about thirty per cent in the world acreage under coco-nuts, bringing the total to 7,000,000 acres in 1931. Since 1921 the British Empire has accounted for slightly more than half this amount. The increase in production has been mainly due to the demand from the United States, but the needs of that country can be met by the production from the Philippines. Other producing countries, including those of the British Empire, must be chiefly dependent upon European consumption. Owing to the heavy production of whale oil, however, there is at present no sign of an increased demand in the European market. In this market the demand for coco-nut oil depends upon the expansion of the soap and margarine industries. The survey concludes that the output of copra will be on the increase for several years and that the bulk of this will appear on the world market, although local consumption accounts for a considerable proportion of the output of most producing countries, especially of India, the Dutch East Indies, and the South Sea Islands.

Science Museum Handbook of Pumping Machinery

THE recently issued handbook to the collection of pumping machinery at the Science Museum (H.M. Stationery Office, 2*s.* 6*d.* net) prepared by Mr. G. F. Westcott, should be of widespread interest. It is not a catalogue to the exhibits but a general introduction to the development of pumps illustrated by drawings and photographs of actual plant or models. The ground it covers extends from the earliest baling appliances to the most recent molecular vacuum pumps. After a general review of what may be called the philosophy of pumping, there are four sections dealing in turn with pumps for liquids, pumps for gases, high vacuum pumps and multiple purpose pumps. There are thirty plates in all, including a reproduction of the Museum chart illustrating the development of pumping machinery. This ingeniously worked-out chart might prove useful in many technical schools. One illustration of great historical interest is that of the famous pumping plant erected at Marly by order of Louis XIV for supplying water from the Seine to the fountains at Versailles. With its fourteen water-wheels, its 253 pumps and its connecting mechanism, it was probably the largest machine ever erected. Its effective horse power, however, was very small and it is said that the King of Denmark once remarked to Louis that his water cost him as much as his wine.

Death Valley a new 'National Monument'

ON February 11, by presidential proclamation, President Hoover gave the status of 'national monument' to Death Valley, famous in the history of California for the hardships endured by pioneer trains crossing its arid, salt-crusted waste (Science Service, Washington, D.C.). A national monument differs from a national park only in respect to grade of protection; administration is simpler, either because of difficulty of access, lack of funds to provide full national park administration, or other reasons. The area of the new monument is 1,601,800 acres, about two-thirds of the total land in the Valley, and its dryness is so great that mineral salts of several varieties form thick crusts upon the surface of the soil. Of these, the borax deposits used to be worked commercially. In spite of its dryness, Death Valley is by no means barren; more than 500 kinds of plants live there and on these subsist many animal species. Some of the notable natural features are Telescope Peak, Furnace Creek, a green valley despite its name, and Ubehebe Crater.

Engineering Research in Japan

THE National Research Council of Japan (Imperial Academy House, Ueno Park, Tokyo) publishes a series of journals or reports each of which deals with some branch of science. Of these, vol. 8 of the *Japanese Journal of Engineering* has recently reached us. This consists of a book of 90 pages containing abstracts of 313 papers read before various scientific and technical societies or contributed to periodicals in 1928. The abstracts are grouped under civil engineering, mechanical engineering, naval architecture, aeronautics, electrical engineering, mine engineering and metallurgy. Though the papers themselves are written in Japanese, the abstracts are in English and for the greater part have been written by the authors of the papers. In general, the subjects dealt with follow the lines of engineering research in other countries, and the volume shows that Japanese engineers have a keen appreciation of the value of original investigation.

Awards of the Royal Geographical Society

HIS MAJESTY THE KING has approved the award of the Royal medals of the Royal Geographical Society as follows: Founder's medal, to Mr. J. M. Wordie, for the work he has done in polar exploration from the voyage of the *Endurance* in the Weddell Sea in 1914–17 to the present day; Patron's medal, to Prof. Erich von Drygalski, for his researches in glaciology both in the arctic and the antarctic regions. The Council has awarded the Murchison grant to Dr. Noel Humphreys, for his expeditions in Ruwenzori; the Back grant to Miss Freya Stark, for her journeys in Luristan; the Cuthbert Peek grant to Dr. L. S. B. Leakey, for his studies on climatic changes in East Africa; and the Gill memorial to Khan Sahib Afraz Gul Khan, of the Survey of India, for his frontier and trans-frontier explorations and surveys.

Announcements

MR. M. T. DAWE, director of agriculture, Cyprus, has been appointed by the Secretary of State for the Colonies to be director of agriculture and forests, Palestine.

THE Gesellschaft Deutscher Naturforscher und Aerzte will not meet this year. The next meeting, the ninety-third, is to be in Hannover in 1934. Local secretaries are: Prof. C. Müller and Prof. Dr. Willige, both of the Technische Hochschule, Hanover.

AT the meeting of the London Mathematical Society on April 27 at 5 p.m. at Burlington House, Prof. B. L. van der Waerden, of the University of Leipzig, will deliver a lecture on "Hypercomplex Numbers". Members of other scientific societies who may be interested are invited to attend.

ARRANGEMENTS are being completed for the holding of the 1933 meeting of the Canadian Phytopathological Society at Regina, Sask., in July, in conjunction with the World's Grain Fair and the C.S.T.A. Convention. A committee under the chairmanship of Dr. P. M. Simmonds, Saskatoon, has been appointed to look after local arrangements. The secretary of the Association is T. G. Major, Central Experimental Farm, Ottawa.

THE papers read at the conference on "Protein Swelling and Allied Phenomena" held at the Leathersellers Hall, E.C.2, on December 1, are being reprinted in book form, including the introductory address by Prof. F. G. Donnan. The book is of about 124 pages, and copies will be shortly obtainable from the Offices of the International Society of Leather Trades Chemists at 17, Market Street, London, S.E.1; price 5*s*. 6*d*., including postage.

THE Quekett Microscopical Club has arranged a series of demonstrations in connexion with microscopy, which are being given on the same evenings as the ordinary fortnightly meetings for the next three months. The meetings are held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1. Tickets for the meetings can be obtained from Mr. Milton Offord, 8, Culmington Road, West Ealing, W.13. A brochure containing lists of recent additions to the library, cabinets and collections of instruments, of the Club has recently been published, price 1*s*. Further information regarding the Club can be obtained from the secretary, Mr. W. S. Warton, 35, Doneraile Street, S.W.6.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An organising mistress for domestic subjects in the North Riding of Yorkshire—The Secretary, Education Offices, County Hall, Northallerton (April 25). A chief engineer and manager of the Government Electrical Undertakings, Ceylon—The Crown Agents for the Colonies, 4 Millbank, Westminster, S.W.1 (April 28). A principal of the City of Leeds Training College—The Director of Education, Education Department, Leeds (April 29). A demonstrator in the Department of Zoology at the Bedford College for Women, Regent's Park, N.W.1 (April 29). A Grade 1 engineering assistant at the Mines Department—The Under-Secretary for Mines, Establishment Branch, Mines Department, Cromwell House, Dean Stanley Street, S.W.1 (May 1). A probationary assistant naval constructor of the Royal Corps of Naval Constructors—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (May 1). A headmaster of the Nautical School and School of Fishermen, Boulevard—The Director of Education, Education Offices, Guildhall, Hull (May 6). A professor of education at the University of Leeds—The Registrar. A junior full-time teacher in the Department of Engineering of the Municipal Technical College, Oldham—The Director of Education, Education Offices, Oldham. An assistant instructor in the School of Navigation at University College, Southampton—The Registrar.

Phenomenal Regression to the Real Object

DR. THOULESS's interesting article in NATURE of February 25 on this subject is of special interest at the present time when physicists, physiologists, and psychologists are co-operating in the solution of problems regarding vision. The terminology and modes of expression are not unusually quite different in the respective branches of investigation, and this makes it very imperative that there should be full mutual discussion regarding the statements involved so as to avoid the possibility of misunderstanding.

The following remarks may err through misunderstanding on my part of Dr. Thouless's exact meaning. But it seems to me that his statement that Fechner's law (expressed in the form $E = k\log(R/R_0)$) implies that there is a single sensation intensity for every stimulus strength may be misinterpreted as to its implications. Clearly, for example, if R_0 is constant while R is a stimulus of variable magnitude but constant quality, the statement holds. But it has to be remembered that the three variables in terms of which, as a minimum, R is usually expressed, may also appear in R_0; and that R_0 is usually dependent also on many other variables. Examples of these are the time which has elapsed since the stimulus began, or the times which have elapsed since preceding stimuli began or ended, or the qualities of these stimuli, or the physiological condition of the observer as dependent on precedent exercise, bodily or mental, and so on. It is evident that, unless these extraneous variables are kept constant, one and the same sensation will not in general result from a definite external stimulus.

Recognition of these conditions has direct application to the interesting cases discussed by Dr. Thouless in which the presence or absence of an additional datum, such as the distance of an object, has influence on the result of the given stimuli. But it is then a matter for experiment to determine the form of the function of that additional datum which, being introduced into the threshold value R_0, will include the more general results within the scope of Fechner's law for single-valued sensation.

This raises the question of whether or not subjective, as well as objective, data should be treated similarly in so far as that may be found possible. The influences of memory, expectation, bias of any type, and so on, have to be eliminated or allowed for as new qualitative or quantitative data. Further, since external action produces mental activity, may not independent mental activity give rise to alteration of these mental activities ? Physical analogies suggest this as a possibility. The scope for investigation on these lines is immense, but its results may not of necessity lie outside the field expressed by Fechner's law.

The interesting results which are indicated in Dr. Thouless's diagram seem to be perhaps in part due to the actual conditions of projection. If the inclined circle be viewed from a sufficiently near point, a marked excess of the apparent short diameter over its normal projection actually exists ; and the curve is not an ellipse. But no rough method of measurement gives an accurate test, while an indirect *guessed* measurement is very liable to error.

W. PEDDIE.

Department of Physics,
University College,
Dundee.
March 2.

I AGREE with Prof. Peddie that the Fechner relationship need not necessarily involve a single sensation strength for every stimulus strength, but that implication is strongly suggested by the habitual statement, as the fundamental law of sensation strength, of a law which expresses this strength as a function of one variable (stimulus strength) and not of three or more. The attitude of mind induced by Fechner's law has certainly been the relative neglect of the effects of spatial and temporal contrast (treating those as mere disturbing factors) and the complete neglect of the effect of the total situation under complex conditions of perception. This seems to be sufficient justification for making Fechner's law the starting point of a description of a quantitative investigation of the effects of the total situation.

I certainly agree that any such variable may affect the absolute threshold in such a way that E remains the same function of R/R_0. I know of no investigation to prove that this is the case. I do not think that the question is important, since the formula $E = k\log(R/R_0)$ is indefensible even for uniform contrast conditions, since it assumes the validity of Weber's law for stimulus values down to the threshold value, which is found experimentally not to be even approximately correct.

Prof. Peddie's last paragraph is based on a misapprehension. If an inclined circle is observed from a near point the short axis of the projected figure will certainly be relatively longer than it would be if the observation were made from an infinite distance when the projected axis-ratio would be equal to $\sin\theta$ (if θ is the angle of inclination of the disc to the line of vision). The error resulting from this miscalculation of the projected axis-ratio would have been small but I did not make this mistake. Nor did I use a rough method of measurement. The only rough measurement I mentioned in my article was for the demonstration of the presence of the effect (not the exact measurement of it) by means of an elongated ellipse. Since the effect is large, it is easily perceptible to rough demonstration. Where, however, quantitative results were required, the measurements and calculations were as accurate as I could make them.

Photosensitised Decomposition of Ozone by Chlorine

THE decomposition of ozone, photosensitised by chlorine, has been the subject of numerous investigations, and it would appear from recent work that the kinetics of this reaction are by no means so simple as at first supposed. In particular, the recent paper of Heidt, Kistiakowsky and Forbes[1] describes a complex dark reaction which occurs simultaneously with the photosensitised decomposition. We have read this paper with great interest, since we have also been engaged in an investigation of this reaction, and whilst our results confirm those contained in this paper, we are unable to agree with the authors' interpretation of them.

We have found that, with pressures of ozone and chlorine above 100 mm. (and light of 365mμ) a red liquid oxide of chlorine separates on the walls of the vessel. The ratio $Cl_2 : O_3$ determined by the method of Schumacher and Stieger[2] agrees closely with the formula $(ClO_3)_n$.

The oxide is presumably to be identified with the mist noted by Allmand and Spinks[3] and by Heidt, Kistiakowsky and Forbes[1]; the former authors note the formation of chloric and perchloric acids, when the mist dissolves in water. As is well known, a similar red oxide, Cl_2O_6, was also described by Bowen[4], by Bodenstein, Harteck and Padelt[5], and by Schumacher and Stieger[2] as formed by the interaction of chlorine dioxide and ozone.

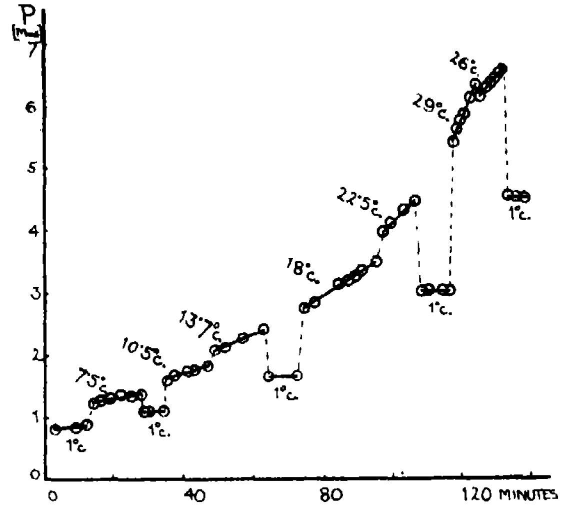

FIG. 1.

It was found that the separation of this oxide was particularly marked at 0° C. A quantity of the oxide was prepared at 0° C. and the excess chlorine, ozone, and oxygen removed by a Hyvac pump while the vessel was cooled to − 10° C.

On warming the oxide it was then found that no constant vapour pressure was shown. On the contrary, a steady increase of pressure occurred, this being negligible at 1°C. and becoming more and more rapid as the temperature rose. On cooling again to 1°C., the original pressure was not regained, showing that an irreversible decomposition had occurred (Fig. 1).

We suggest that the phenomena noted by Heidt, Kistiakowsky and Forbes are explicable in terms of the separation of this oxide, which, according to our experiments, should have occurred under the conditions adopted by them, namely, high chlorine and ozone pressures and an initial temperature of 2°C.

The continued increase of pressure after the light was cut off noted by them, indicates the (thermal) decomposition of this oxide film; it is to be noted that, according to their experiments, this did not occur until after the gases had been illuminated for a considerable period, as is to be expected, according to this hypothesis.

We find a temperature coefficient of 2·34 per 10° C. for the decomposition of the oxide; this is of the same order as that noted by Heidt, Kistiakowsky and Forbes for their "dark reaction". Our apparatus is essentially similar to that used by them, and on account of the separation of the oxide we have not attempted to measure quantum efficiencies at chlorine pressures above 100 mm., since it is impossible to do so by pressure increase. Our results at lower pressures of ozone and chlorine indicate, on the other hand, that reproducible results are obtained when separation of the oxide is not allowed to occur, and that, while inert gases have no effect on the course of the reaction, oxygen had a distinct inhibiting effect. These results will shortly be published elsewhere.

Electrometer Triode in the X-ray Ionisation Spectrometer

MR. J. A. C. TEEGAN, writing in NATURE of February 25, mentions that the application of the electrometer triode to X-ray ionisation spectrometers is under consideration. I have successfully used this valve for this purpose during the past three years and saw it in use in Germany even earlier.

In the earlier measurements in this laboratory, the grid of the valve was not connected to the filament through a high resistance. X-rays were allowed to pass into the ionisation chamber for a suitable interval, generally 10 sec., and the charge collected on the insulated electrode was measured by the change in anode current of the electrometer triode. This is usually of the order of one microampere and may be measured directly by a galvanometer. This is the most sensitive method of using the valve.

Following Dr. B. W. Robinson, of the Davy-Faraday Laboratory, it is now the practice here to connect the grid to the filament by a high-resistance leak (pencil line on amber) in which case the steady deflection of the galvanometer measures the ionisation current. The anode current when no X-rays are entering the chamber is compensated by a potentiometer arrangement and the circuit is essentially the same as that given in the diagram of Mr. Teegan's letter.

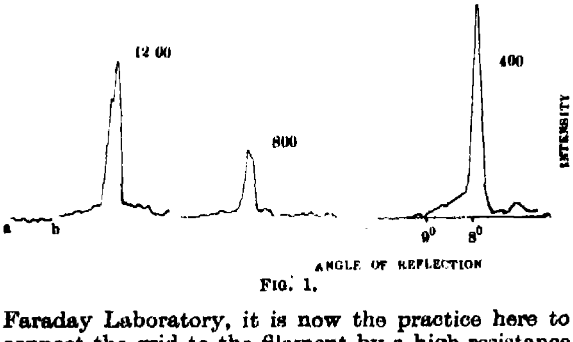

FIG. 1.

For most measurements a semi-automatic recording device is used. The ionisation chamber is set at the required angle and the crystal rotated through the reflecting angle by means of a worm-driven wheel.

The same driver causes a drum carrying paper to pass under a pen which is moved by hand along guides parallel to the axis of the drum so that it follows the deflection of the galvanometer spot. The curves in Fig. 1 were obtained in this way: the ordinates, being the deflections of the galvanometer, measure the intensity of the reflected X-rays and the abscissæ give the rotation of the crystal.

The curves were obtained by passing molybdenum $K\alpha$ radiation, filtered through zirconium metal, through a thin plate of gypsum so that orders (400), (800), (1200) could reflect at angles of 8°, 16°, 24° approximately. The crystal turns through 1° in 1·6 minutes and this corresponds to the paper moving forward by 2·8 cm. This enables measurements to be made much more quickly than was possible with the earlier arrangement. The steadiness of the zero is indicated by the line *ab*, which was obtained with the X-rays cut off, and the sensitivity may be estimated from the fact that the X-rays used for the curves shown produced a barely visible fluorescence in a darkened room on a barium platinocyanide screen.

The apparatus is simple to set up and very reliable. Precautions must be taken to shield the valve electrostatically but the galvanometer need not be so protected. The total cost of the apparatus is less than that of the usual electrometer systems used for the same purpose.

W. A. Wooster.

Department of Mineralogy and Petrology,

Feb. 25.

In Nature of February 25, Mr. J. A. C. Teegan proposed to apply the 'electrometer valve' now produced commercially by the G.E.C. to an X-ray ionisation spectrometer for the amplification of ionisation currents. It may interest him to know that such a valve has been in use for this purpose in this Laboratory for the past eighteen months with success, using a circuit identical in all essentials with that which he describes.

The G.E.C. valve is simpler in construction than the FP 54 pliotron described some years ago by Messrs. Metcalf and Thompson for a similar purpose in the *Physical Review*; I think, however, that it is not quite so sensitive as the American valve.

To take full advantage of the G.E.C. valve used with an ionisation spectrometer, the indicating galvanometer should have a quick period (1 sec.) and sensitivity of the order of 100 divisions per microampere. I do not know whether such a galvanometer can be obtained cheaply; one can be made quite easily, since high resistance in the galvanometer coils (25,000 ohms) is of no particular disadvantage in this circuit.

High-Frequency Electric Discharge in Gases

In October 1929, while using a radio-frequency oscillator of the tuned-plate/tuned-grid type (Fig. 1) for exciting the capacitive electrodeless discharge photographed by J. and W. Taylor[1] in gases at low pressure, I observed phenomena which have not, I believe, been elsewhere described.

The frequency employed ranged from 11·1 megacycles sec.^{-1} to 21·4 megacycles sec.^{-1}; the valve was a power-oscillator of the *VO* 150 type with 1,800 volts anode potential supplied by accumulators, and the anode current ranged from 150 milliamperes to 160 milliamperes at these frequencies respectively. The anode inductance comprised three to four turns of 12 gauge wire, and to excite the discharge two wires were attached by clips to turns at opposite ends of the coil and their other ends were tightly bound round the ends of an ordinary positive column tube of about 18 cm. cylindrical length by 1·3 cm. internal diameter filled with neon with but slight traces of unknown admixture at approximately 8·0 mm. mercury pressure. The cylindrical sheath electrodes fused into the frusta-conical bulbs at the ends of the tube (Fig. 2) were not connected.

Originally, excitation of luminosity by the method used by Prof. R. W. Wood and A. L. Loomis[2] was in view, but in certain conditions, discharges were obtained of a curious nature: when the plate and grid circuits of the oscillator were closely in tune, a single streamer ran longitudinally through the tube, but instead of being straight and lying approximately along the axis of the tube, the streamer appeared bent somewhat into the shape of an elongated sine-wave of one complete cycle. When the frequency to which the grid circuit was tuned was slowly caused to diverge from that of the anode circuit, the streamer began to rotate at an accelerating rate about the axis of the tube, the sense of rotation depending upon the direction of divergence. At the same time, the streamer took on a helical conformation of one turn. With increasing divergence the speed of rotation increased until the whole tube appeared filled with glowing gas; with further divergence the discharge resolved itself into two inter-twined helical streamers revolving together but in the opposite sense to that of the single streamer. As the divergence continued to increase the angular velocity of the inter-twined streamers decreased to zero (Fig. 2), reversed and increased again until the tube was filled with a blur of light, and this cycle of phases was repeated with the periodic intercalation of an additional strand to the multiple streamer up to sixteen or seventeen strands, when they became difficult to count.

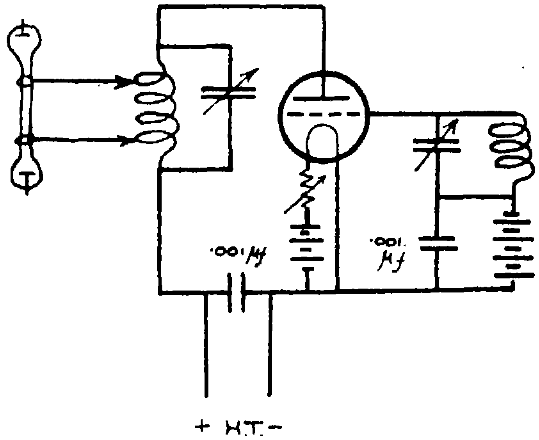

Fig 1.

This discharge was exceedingly difficult to produce at will: usually the form was that shown in Fig. 3, in J. and W. Taylor's article, but by breaking and making the anode supply circuit many times in succession, rotary streamers generally appeared. The distance between the capacitive electrodes was immaterial to inception and appearance, and orientation of the tube with respect to the coil or to a permanent magnet appeared to be without sensible effect. Once started, the discharge was extremely stable, and the envelope temperature was of the order of 40°–50° C.

Occasionally, only about half the distance between the external electrodes would exhibit rotary streamers while the remainder would contain a stationary, co-axial, thicker column (Fig. 3). A rotary discharge also occurred more frequently between the bright rings immediately within the capacitive electrodes and the unconnected sheath electrodes in the bulbs, always with a large number of strands (Fig. 4).

In explanation, I tentatively suggest that the electronic displacement current and the corresponding equivalent accelerating potential difference between two points in the gas (between which the displacement current is drifting) are out of phase to an extent depending upon the divergence of natural frequencies of tuned-grid and tuned-anode circuits of the oscillator, and the result is that an electron if it were originally at rest within the tube would describe, in the absence of collisions, a zig-zag path round an annulus inside the walls; the net effect of a large number of electrons doing this gives in general a rotary helical locus of maximum electronic velocity (and therefore of ionisations-by-collision). The suggested effect of phase difference, though a purely *ad hoc* supposition, would appear to be substantiated to a certain extent by equations (7) and (8) given by Darrow in a recent paper on "High Frequency Phenomena in Gases"[3].

Hydraulic Seismographs

PROF. KAPITZA has described[1] a balance for the measurement of magnetisation in which he makes use of hydraulic magnification and damping in a very ingenious manner and suggests that the same method may be adopted for the construction of seismographs. In order to explore the possibilities of this type of instrument for the recording of earthquakes a series of comprehensive experiments was carried out by us in the Colaba Observatory.

The apparatus for the recording of the vertical component consists of an inverted cylindrical cup, its lower horizontal face being closed by a thin metal diaphragm and a narrow open tube being attached horizontally fitting a hole in the side in which a mirror is suspended from a horizontal axle. A cylindrical jacket covers the cup all round except the diaphragm at the bottom. A highly viscous oil is then poured into the double chambers, so as to fill up completely the inner chamber, and the diaphragm is then loaded by attaching a weight of 1 kgm. or more to a rod fixed at its centre. The vertical component of the ground movements sets up oscillations in the diaphragm and forces the oil to move to and fro through the narrow tube, and this gives a large oscillatory angular motion to the mirror which is recorded photographically. With a tin diaphragm of thickness 0·019 cm. and diameter 15 cm. loaded with 1 kgm., a period of 2·3 sec. and a damping ratio of 5 : 1 were obtained when the instrument was filled with castor oil.

The low free period of the system does not make the instrument very sensitive to earthquake waves. It is, however, highly sensitive to artificial vibrations of the ground and gives also good records of the sustained vibrations, such as microseisms. Being a compact and fully assembled portable instrument it should form a valuable equipment for geophysical prospecting.

If the chambers be so arranged that the membrane is in the vertical plane and is loaded with two symmetrical weights fixed at both ends of a horizontal rod passing through its centre, the instrument records the horizontal component of the ground movements. The sensitiveness to earthquakes of the instruments for horizontal and vertical components is increased if the free period of the system is increased by using membranes of very large diameters. A leather or rubber membrane slightly increases the sensitiveness, but generally produces an unstable 'zero'. A detailed account of the investigation will be published in due course.

Reversal of Current in Rectifier Photo-Cells

WE have noted with interest Mr. Guild's observations on this effect, as recorded in NATURE of March 4. In reply to his query, the values given for the relative sensitivities were for an "equal energy spectrum", being obtained by direct comparison with a Moll vacuum thermopile for the different spectrum regions. Any other method of presentation would obviously be valueless, as the energy flux reaching the cell increased rapidly with the wave-length. The maximum reverse current obtained from the marginal regions of the cell was no less than 28·5 per cent of the maximum direct current obtained for the same regions.

We should like to take this opportunity of apologising to Dr. P. Auger and M. C. Lapicque for having overlooked the section of their paper[1] in which they briefly mention the reversal phenomenon, and give its explanation, identical with the one since given by us and by Mr. Guild. Dr. Auger also studied the spectral transparency of such gold and silver films, as Mr. Guild is now doing; from this he deduced the true variation in the spectrum of the photo-electric properties of cuprous oxide, since the curves given by gold and silver film cells were identical when corrected for the transmission of the film. The transmission of cuprous oxide films has been studied by L. Dubar[2], who investigated also the temperature coefficient of the cells up to 60° C. Dubar[3] has also studied the peculiar constitution of the cuprous oxide layer.

A Rule for the Rotatory Direction of the Acetylated Aldonic Nitriles

During research on some sugar derivatives, the rotation in chloroform of their acetylated aldonic nitriles was determined, and the following results were obtained:

tetra-acetyl *d*-xylonic nitrile,	$(\alpha)_D^{22} = +50{\cdot}3°$;
tetra-acetyl *l*-arabonic nitrile,	$(\alpha)_D^{22} = +\ 4{\cdot}2°$;
penta-acetyl *d*-galactonic nitrile,	$(\alpha)_D^{22} = +48{\cdot}4°$.

From a search in the literature, the rotations determined for other nitriles were found to be:

penta-acetyl *d*-gluconic nitrile[1,2], $(\alpha)_D^{22} = +46{\cdot}2°; +48{\cdot}0°$;
hexa-acetyl *d*-gluco-α-heptonic nitrile[4], $(\alpha)_D^{22} = +24{\cdot}6°$;
hexa-acetyl *d*-manno-α-heptonic nitrile[3] $(\alpha)_D^{20} = +31{\cdot}4°$;
penta-acetyl *d*-mannonic nitrile[2], $(\alpha)_D^{20} = -\ 1{\cdot}4°$;
penta-acetyl *l*-rhamno-α-hexonic nitrile[3], $(\alpha)_D^{20} = -76{\cdot}4°$.

The following data were found for non-acetylated aldonic nitriles:

gluconic nitrile[4]	$(\alpha)_D^{22} = +\ 8{\cdot}8°$;
d-manno-α-heptonic nitrile[3],	$(\alpha)_D^{20} = +23{\cdot}1°$;
l-rhamno-α-hexonic nitrile[3],	$(\alpha)_D^{20} = -23{\cdot}4°$.

When the figures and signs of rotation of the acetylated nitriles are compared, it is seen that a new rule similar to the well-known amide or phenylhydrazide rules of Hudson for aldonic acids, can also be formulated for the acetylated nitriles of the same acids.

When the configuration of the 2-carbon atom is considered, it follows that nitriles in which that atom has the configuration $\mathrm{H\overset{|}{\underset{|}{C}}O.COCH_3}$ (that is, $\mathrm{H\overset{|}{\underset{|}{C}}OH}$ in the primitive monose, employing Fischer's projection formula) rotates to the right, as is found in *d*-xylonic, *l*-arabonic, *d*-galactonic, *d*-gluconic, *d*-gluco-α-heptonic, and *d*-manno-α-heptonic acetylated nitriles.

When the configuration of the 2-carbon atom is reversed: $\mathrm{CH_3CO.O\overset{|}{\underset{|}{C}}H}$ (that is, $\mathrm{HO\overset{|}{\underset{|}{C}}H}$ in the primitive monose) the nitriles rotate to the left, as in *d*-mannonic, and *l*-rhamno-α-hexonic acetylated nitriles. It follows that the sign of rotation of the nitriles will be the same as that of the amides and phenylhydrazines of the same acids. It is of no use, however, to make comparisons between the rotatory values of the acetylated nitriles and the amides or the free acids, owing to the different solvents employed in each case.

The theoretical foundations of the nitrile rule are the same as those for the amides or the phenylhydrazides, and have been explained by Kuhn and Freudenberg. Only exaltation of the individual asymmetric carbon atoms must happen owing to acetylation of the alcoholic hydroxyls. When the free nitriles are considered, it is seen that perhaps the rule can also be applied to them, although the examples are few in number.

Work is now being done with other members of the same group to see if they accord, as we expect, to the rule. It is hoped to include some α-oxy acids.

Zones of Apparent Inhibition of Sunspots on the Solar Disc

In a recent paper[1] referred to in Nature of February 18, p. 245, Mr. P. R. Chidambara Aiyar reports the result of an analysis of the distribution over the visible portion of the sun of sunspots lasting two days, and finds that his curves of distribution show, in addition to a maximum at the centre of the disc, maxima at longitudes about 15° inside either limb. This he describes in terms of the intervening minima by calling their positions zones of apparent inhibition of spots.

It is to be expected that the number of spots of any given size or period observed, in an assigned number of degrees of longitude, would show a steady diminution from centre to limb simply on account of foreshortening rendering the spots less visible. The minima noted by Mr. Aiyar can scarcely have a physical significance since the co-ordinates used (apparent longitude on the solar disc) have no physical meaning for the sun, being fixed on any day by the position of the earth in its orbit on that day.

Mr. Aiyar has established that his results are not due to random variations in the data, and accordingly a cause lying in the mode of selection of the data is to be sought. I wish to point out that the explanation of the inhibitory zones is to be found in the following reason for the existence of the maxima near the limb, and that there is in fact no region of scarcity, but merely a spurious region of richness.

In selecting the spots, only those are used which are observed on two days, but not on three or more. If the whole surface of the sun were visible this selection would operate uniformly in all solar longitudes, but in fact only the region from − 90° to + 90° is visible at any one time, and this leads to an excessive count near the limb. Owing to the rotation of the sun, a spot travels about 15° per day, so that all spots between longitudes − 60° and + 60° are observable during two days or more; hence all spots occurring in this region are excluded from the count if their life exceeds two days, while spots in the remaining regions are observable for two days *or less*. Taking − 90° as the limb of the sun which is rotating towards the earth, all spots classified as two day spots between about − 90° and − 60° may in fact have had any life up to about 16 days, and similarly all spots classified as two day spots between about + 60° and + 90° may have a life of from two days up to about 16 days, that is, in either zone half a revolution period of the sun plus rather more than two days. Actually the limits 60° and 90° must be replaced by somewhat smaller values to allow for the loss of spots by foreshortening, and in any event the foreshortening conquers at the limb where the number must finally fall off.

Thus we are to expect spurious maxima at about ± 75° due to this selection, and this is precisely where Mr. Aiyar finds his extra maxima.

A more detailed numerical investigation will be described later.

Further Light on the Schneider Mediumship

I have read the review in Nature of April 8 of Mr. Harry Price's "An Account of some Further Experiments with Rudi Schneider". To deal in detail with the charge of fraud brought by Mr. Price against Schneider in his report would take up more space than could be afforded in these columns. I have, however, been closely associated with all the experiments which have been made with this medium in England (April 1929 to December 1932), and I would ask all who are interested in these matters to withhold their judgment until a report has been published of further experiments held with this medium (October to December 1932). These further experiments were carried out in as scientific and impartial a manner as circumstances permitted and the results supplied strong indications that Schneider indeed possesses genuine 'supernormal faculties'.

In reply to the suggestion put forward in the review in question that the presence of a supposed accomplice invalidates Dr. E. Osty's report "Les Pouvoirs Inconnus de l'Esprit sur la Matière"—a report of careful experiments with the same medium, 1930–1931—it appears that the attempts of trickery in question were of a puerile order and in no way affected the main issue. The infra-red ray apparatus and objects subjected to telekinesis were completely separated from the medium and sitters by a clamped gauze net, 5 feet 6 inches high, and none of the attempts at trickery affected any phenomena on the far side of the net. Out of a total of ninety séances held by Dr. Osty, the suspect attended only fifteen, of which seven were blank and at none was telekinesis reported.

It should be noted that Mr. Price did not notify his Council or any of his invited sitters of (1) the existence of the incriminating photograph, (2) the friendly warning of Dr. Osty with regard to the suspect who, however, was allowed by Mr. Price to attend all the séances arranged by him.

It is hoped to carry out still further experiments with the same medium later this year, when various improvements will be adopted concerning both the technique of the séances and the scientific apparatus employed.

Tracheal and Blood Gills in Aquatic Insect Larvæ

Among the larvæ of aquatic insects, two fairly well-defined types of gill-like structures are commonly found—'tracheal gills' and 'blood gills'. The former term is applied to thin plates or filaments with a copious tracheal supply and only a very small blood cavity, structures which are typically developed in such insects as Ephemeroptera and Trichoptera. The term 'blood gill' is restricted to organs which have a spacious lumen but in which tracheæ are poorly developed or totally absent; the ventral and anal gills of *Chironomus* being a familiar example. The work of Fox[1] on *Chironomus* gave rise to doubt as to the respiratory function of blood gills in general, doubt which has been strengthened by the confirmatory work of Harnisch[2], and in a recent series of papers Wigglesworth[3] describes experiments upon the anal gills* of the larva of the yellow-fever mosquito (*Aedes* (*Stegomyia*) *argentatus*), from which he concludes that the main function of these structures is the absorption of water and that they are of little value as organs of respiration. Since in this species they are much larger than in the majority of allied forms, it is probably safe to assume that in the Culicidæ as a whole, anal gills are of little importance from the point of view of respiration: a conclusion which is confirmed by my own experiments on *Culex* spp.

In view of these results, it seems opportune to give a brief summary of experiments on blood gills and tracheal gills in other aquatic larvæ which I have carried out, a preliminary account of which is already in the press[4]. The technique employed was similar to that described in a previous paper[5]. In the case of the rectal blood gills of Trichoptera, it was not possible to detect any respiratory function, and similar results were obtained with the rectal gills of *Simulium*, *Corethra*, etc. One can therefore state that in *no* case has it been shown that the blood gills of aquatic larvæ serve any useful function in respiration. While there remains the possibility that these structures may come into play only within certain limits of oxygen tension, it may be said that the work of Harnisch gives no support to this hypothesis even in that form (*Chironomus*) in which it would appear most probable.

As might be expected, experiments with tracheal gills have yielded different results and have shown that these organs are undoubtedly active in respiration. But it has long been known that the larvæ of Agrionid dragon-flies can survive for a considerable period in the absence of caudal lamellæ and Cuenot[6] showed that the tracheal gills of certain Ephemeroptera (*Ephemera*, *Chloeon*) can be removed without causing the death of the insect. In the Agrionids, the existence of general cutaneous respiration is easily demonstrated and my observations have shown that cutaneous respiration is also very prevalent among Ephemeroptera (*Chloeon*), Trichoptera (*Limnophilus*, *Anabolia*, *Leptocera*), Coleoptera (*Gyrinus*) and Neuroptera (*Sialis*), although in every case the tracheal gills are undoubtedly acting more or less efficiently. Since these observations were made, it has been shown[7] that the gills of the Ephemerid *Hexagenia recurvata* are not essential to life in the winter months and that[8] even the elaborate gills of the Caddis *Macronema zebratum* are superfluous: the insect being capable of completing its life history without them.

In certain genera of Plecoptera tracheal gills are poorly developed and in some instances, by no means small forms, they are lacking altogether, so that gaseous exchange takes place entirely through the general body surface. Experiments with larvæ of a species of *Leuctra* which lacks tracheal gills entirely showed that respiration proceeds most rapidly at the ventral surface of the thorax and the bases of the legs, the indicators being affected later at the 'neck' and at the anterior region of the abdomen. In view of this, it is interesting to note that an American species of *Nemoura* has been described[9] as having the walls of the femora richly supplied with tracheæ as if to serve as a gill.

Tracheal gills are rare among dipterous larvæ. Such gills with a large tracheal supply occur in Tipulids (for example, *Pedicia*) and in the curious larvæ of the Pantophthalmidæ, but in each case open spiracles are present, and although the gills have been shown[10] to be the site of very rapid gas exchange compared to the rest of the body, it is known[11] that the larva (*Pedicia*) cannot long survive occlusion of the spiracles. They are at best a rather unimportant accessory means of respiration.

To sum up, it can be said that the blood gills found in aquatic insect larvæ are practically negligible so far as respiration is concerned, and to this extent the conclusions of Wigglesworth are supported. Certain types of tracheal gills, on the other hand, may be very efficient. But they are by no means the sole organs of respiration and even where highly developed, may be secondary in importance to the general body surface; under experimental conditions the animal can often do without them for long periods if not altogether.

[*] Owing to their small tracheal supply and relatively large blood space the anal gills of mosquito larvæ are here classed as 'blood gills' rather than 'tracheal gills'.

Earthquakes in the Holy Land: A Correction

In an article on earthquakes in the Holy Land[1] there is given a list of 207 shocks, of which there is record, between the years 1606 b.c. and a.d. 1927. Among these are 27 dates from an Arabian authority, As-Soyuti, whose work appears in translation in the *Journal of the Asiatic Society of Bengal*. In transcribing those dates I failed to observe that they were stated as a.h., that is, *Anno Hejira*, instead of *Anno Domini*. They are, therefore, as quoted in my list something over six centuries too early. The corrected dates are as follows:

A.H.	A.D.	A.H.	A.D.	A.H.	A.D.
94	712	434	1042	552	1157
98	716	455	1063	565	1169
130	747	460	1067	575	1179
220	835	462	1069	578	1182
233	847	479	1086	597	1200
242	856	484	1091	600	1203
245	859	532	1137	702	1302
393	1002	538	1143	791	1388
425	1033	551	1156	889	1484

Inasmuch as the Hejira dates from July 622 a.d. and there are adjustments of the calendar dates for fractions, these figures may be off one year. It is also probable that the original dates are approximate. Hence where As-Soyuti differs by a year from others given in the list as published, one shock only is presumably meant.

In this connexion I would direct attention to a very ancient, yet definite observation regarding the now well-known earthquake fault that traverses the eastern slope of the Mount of Olives:

"And His feet shall stand . . . . upon the mount of Olives, which in that day *is* before Jerusalem on the east, and the mount of Olives shall cleave in the midst thereof toward the east and toward the west, *and there shall be* a very great valley; and half of the mountain shall remove toward the north, and half of it toward the south."[2]

Activity on this fault was the occasion of destructive tremors in 1927. That it was the scene of more obvious displacement some 2,500 years earlier we cannot doubt in view of the graphic description of the Old Testament writer, although his identity and the exact date of his prophecy are matters of uncertainty, especially with reference to this particular passage.

A Numerical Coincidence

In "The Expanding Universe" Sir Arthur Eddington refers to the *fine-structure constant*, which appears to be a fundamental in the modern physics of which he treats, as a pure number the value of which is close to, if not exactly, 137, and in a later passage he writes: "nature's curious choice of certain numbers such as 137 in her scheme."

There is no indication that Sir Arthur includes the following facts in his thesis but it is undoubtedly the case that the number 137 is remarkable because it is the logarithm of itself, or, to be more precise, 13713 is the mantissa to five decimal places of the logarithm of 13713. Also the reciprocal of 13713 used as circular measure is the value of the usual symbol for the rate of rotation of the earth, it being the angle through which the earth turns in one second of mean solar time.

These things are mentioned as an interesting coincidence in an excellent but perhaps little known book, "A Few Chapters in Astronomy", by Claudius Kennedy, first published in 1894. The resemblance of this salient number to one in a very different connexion may well be taken as an example of Nature's whimsicality.

Research Items

Age of Maglemose in Britain. The evidence for dating the three Maglemose harpoons, which have been found in Britain, by means of the pollen deposits in peat, is discussed by H. and M. E. Godwin in *Antiquity* for March. Of the two harpoons from Holderness in Yorkshire, the Skipsea example was found below 5 ft. of peat with remains of reindeer and an *Ancylus* fauna. Samples of the peat deposit, which is 7 ft. thick with brown sandy silt below, show an immigration and rise of *Alnus* with a diminishing *Pinus*, a high initial percentage of *Corylus*, falling rapidly, but with a pronounced secondary maximum, a small percentage of *Salix* and *Tilia*, and *Ulmus* and *Quercus* showing high percentage values in the lower samples. These conditions are characteristic of the Boreal period, the actual site of discovery being late Boreal. A 'moorlog' sample trawled from the North Sea between the Leman and Ower banks off the coast of Norfolk, the point from which a Maglemose harpoon was trawled in the summer of 1932 [this should be September, 1931], showed an absence of alder, a virtual absence of elm and an absence of oak from the basal sample, and suggests that this harpoon is rather older and of early Boreal age. The attempt to obtain samples of peat from the Hornsea site in Holderness, from which the second of the Yorkshire specimens came, was unsuccessful. Turning to analogous finds on the Continent, the artefacts from Kunda in Esthonia came from a layer of 'bleke', a fresh-water calcareous deposit of the Kunda sea, overlying clay with sub-arctic plants and *Betula*, *Pinus* and *Salix*. The Kunda artefacts can be dated with certainty as of Boreal age and correlated with the *Ancylus* maximum. The *Pinus* maximum and fall, the diminishing *Betula*, the increasing *Alnus* and the immigrant *Ulmus*, with *Quercus* not yet present, characterise the Boreal period for the more northerly parts of Europe. Forest development seems to have been synchronous in Esthonia, Denmark and England and the Maglemose cultures of each were approximately contemporaneous.

Saharan Rock-Engravings. "L'Adrat Ahnet : Contribution à l'Etude archéologique d'un District Saharien" (*Tr. et Mém. de l'Institut d'Ethnologie*, Paris. T. 19) by Dr. Th. Monod contains, *inter alia*, the results of an examination of a large number of rock engravings and inscriptions. These have been recorded on thirty-six sites, of which the author has visited twenty-nine. The problem of the age of these engravings, in default of data, seems insoluble. A certain criterion of relative age is afforded by the weathering of the engraved lines ; but this ceases to be an indication when once they have toned down to the tint of the surrounding surface of the limestone. It does not seem possible to relate the engraving with certainty to the chronological and classificatory schemes suggested for the rock engravings of Northern Africa, especially as these are not themselves convincing. The only classification that appears possible is into two groups according to the subjects :—(1) a pre-camel bovidian group and (2) a camel (equine) group. Of these the first is the older and the artists might well have been the ancient agricultural black population of the Sahara, possibly neolithic ; while the second might have been exclusively Libyo-Berber and historic. The first group is characterised by a remarkable profusion of Bovidæ and by typical African fauna, elephants, giraffe, rhinoceros (?) ; but neither camel nor horse is present ; human figures are without the 'Libyan forelock' and are armed with bows and throwing-knives (?). The engravings have a dark patina. The bow, often shown on South Algerian engravings, is possibly an Ethiopian characteristic. In the second, the camel group, there are no elephants or giraffe (?), camels and horses appear, and the human figures show the 'Libyan forelock' and are armed with a round buckler, three javelins with metal tip and a sword which hangs from the buckler arm. Many show marked steatopygia. The patination is light in colour.

Distribution of Birds of the Russian Altai and north-west Mongolia. A posthumous paper by P. Sushkin has recently been published (*Bull. Soc. Nat. Moscou*, 41, Nos. 1–2) in view of the increasing trend towards mid-Siberian investigation. A description of the topography and vegetation of the area precedes a list of 373 species and sub-species of birds, tabulated according to district and the nature of their stay. Excluding occasional species, about ninety per cent of the forms are classed as 'nesting'. Conclusions are drawn as regards the division of the territory in relation to its fauna. In addition, 26 new, probably new, and imperfectly known sub-species are described in both Russian and English. The contribution gains additional importance from the fact that the author considered the list practically exhaustive for the area. It is to be regretted that lack of space made it impossible to include the entire work, with photographs, etc.

Worms parasitic in Cetacea. Dr. H. A. Baylis has compiled a useful catalogue of the parasitic worms of Cetacea ("Discovery" Reports, 6, 393–418 ; 1932). The first section of the work includes a list of the parasites, in which are given the synonyms of each species, the hosts from which they have been recorded, and references to the principal publications in which the species are described or discussed. The recorded species of trematodes are eighteen, of cestodes sixteen with three which can only be placed generically, of nematodes twenty-four besides two larval forms and one doubtful species, and of *Acanthocephala* seven species and two worms only generically determinable. The second part of the work consists of a list of hosts with the parasites recorded from each and is followed by a bibliography.

Spider Crabs from Japan. Eleven species of Japanese Oxyrhyncha belonging to ten genera are described by Dr. Tsune Sakai in the Science Reports of the Tokyo Bunrika Daigaku, Section B., No. 4, 1932 ; Zoological Institute, Tokyo University of Literature and Science ("Notes on some Rare Materials of Japanese Oxyrhyncha"). New information on some rare forms is given, two of the species are new and five are recorded for the first time from Japan. Most of them are inhabitants of Indian and tropical seas. *Halicarcinus orientalis* n.sp. is peculiarly interesting because this genus is usually found in the southern hemisphere only. The second new species, *Archæopsis rostrata*, is closely allied to *A. thomsoni* but has much broader rostral horns which are more prominent than any known species of the genus. All these crabs vary greatly and a good series of specimens was available in most of them, thus linking up the extreme forms which might have been regarded as separate species. The full-grown male of *Naxia hystrix* is described for the first time, the previous descriptions being mainly from young females. Young and adults of both sexes were abundant and showed very important differences both with regard to the sexes and in development. The carapace in the adult is globular but in the young it is longer than broad, and the rostral horns in the adult are much shorter in proportion to the carapace than they are in the young.

Hybrid Bananas. The search for a banana which is immune to Panama disease is leading to interesting results. At the Imperial College of Tropical Agriculture, Mr. E. E. Cheesman is making genetical studies of bananas, and some of the results are reported in two recent papers (*J. Genetics*, vol. 26, No. 3). As the cytological findings are of much interest, it is hoped that the fixation may be somewhat improved. Previous workers have concluded that the chromosome numbers in cultivated bananas were multiples of 8 or 4, but Mr. Cheesman finds that 11 is probably the basal number, though secondary pairing in meiosis indicates that this may have been derived from an original eight. The sterile and parthenocarpic Gros Michel banana is found to be triploid ($2n = 33$). When pollinated by a diploid variety of *Musa malaccensis* ($2n = 22$) a few seeds are formed, less than one in a hundred flowers. From such seeds ten plants were raised, eight of which were like the female parent and had $2n = 44$ chromosomes. The other two were thick-leaved, sterile dwarfs with about 75 chromosomes. One of the F_1 plants with 44 chromosomes differed from the rest in being immune to Panama disease. This plant (*I.C.*1) showed a high degree of self-incompatibility when selfed, but yielded five offspring, three of which had 44 chromosomes and two 46. Attempts to cross Gros Michel with the pollen of the immune plants yielded one seedling only, which had about 39 chromosomes. The F_1 back-crosses, however, readily with the original male parent, giving vigorous plants having 33 somatic chromosomes. The Mysore banana, which appears to be immune, and has $2n = 33$ chromosomes, was also pollinated by *M. malaccensis* and yielded more seeds. Nine F_1 hybrids were raised. Six of them resembled the female parent and had $2n = 44$ chromosomes, two were thick-leaved dwarfs like those of the Gros Michel cross, and one with $2n = 33$ was intermediate between the parents. Mysore × *I.C.*1 gave two plants, both thick-leaved. One had $2n = \pm 55$ chromosomes, and the other, a dwarf, ± 90. Several other mutant types of dwarf bananas from various sources are briefly described in *Tropical Agriculture*, vol. 10, No. 1.

Motion of a Cone at High Speeds in Air. When a body moves through air at a uniform speed greater than that of sound, it is well known that a 'shock' wave is produced which moves with the body. This wave is very characteristic of photographs of flying bullets. Taylor and Maccoll have given (*Proc. Roy. Soc.*, Feb.) a solution of the hydrodynamical equations which satisfies the condition that the flow is irrotational and that the surfaces of constant pressure, constant velocity and constant density are cones coaxial with the projectile and have the same vertex. The solution was obtained by numerical integration and was used for calculating the pressure at the surface of the cone and the shape of the shock wave. It is found that the conical regime is only possible for projectile velocities above a critical value, which is 1·46 times the velocity of sound for a 60° cone. The theory was tested by measuring the pressures at the surface of cones mounted in the high-speed wind tunnel at the National Physical Laboratory and satisfactory agreement with calculation was obtained. Photographs of flying, conically-nosed bullets were made at Woolwich which showed the breakdown of the conical regime at low speeds. At high speeds the shock wave was a true cone in contact with the vertex of the bullet, while at lower speeds the wave has a curved nose and travels ahead of the bullet.

Predictions of Nuclear Moments. Almost as soon as the neutron was discovered, it was suggested by various authors that the neutron must be a constituent of other nuclei, and it is now generally realised that the well-known difficulties with respect to the nuclear moment and statistics of nitrogen, etc., can be avoided, if the neutron be assumed to have half a quantum of angular momentum, and to obey the exclusion principle. In two recent papers in *Current Science* (Nov. 1932 and Feb. 1933), Prof. B. Venkatesachar and T. S. Subbaraya have applied this model to make more detailed predictions of nuclear moments. They assume that all the protons combine with neutrons to form α-particles, except for an odd proton if the atomic number is odd; the remaining neutrons arrange themselves in levels in the same way as the planetary electrons in an atom. The several possible values of the nuclear moment j may be written down in each case. The values of j determined from the hyperfine structure and from the band spectra are shown to be in agreement with one of the calculated values, except in a few cases.

Measurement of X-Ray Tube Current and Voltage. G. W. C. Kaye and G. E. Bell of the National Physical Laboratory read a helpful paper on the measurement of X-ray tube current and voltage to the Institution of Electrical Engineers on March 30. From the point of view of the X-ray worker, measurements of tube current and of exciting voltage are only a means to an end. They help him to form an estimate of the amount and quality of the radiation he is using. In the case of two types of commercial X-ray tubes—the Coolidge and the Metalix—they found that the output was proportional to the product of the current by the nth power of the peak voltage. In the case of unfiltered radiation from a tube with a thin window n was about unity, but for heavily filtered radiation n might be so great as five. The various types of valve rectification circuits suitable for X-ray work were discussed. It is proved that for like values of peak voltage and milliammeter readings for full-wave and half-wave rectification, the radiation outputs are the same over a pressure range from 40 to 80 kilovolts. The output for constant voltage is about 1·8 times greater. From the radiation point of view the essential factors of voltage excitation are the peak value and the form of the wave. The several methods of measuring high voltages are dealt with in detail. It is pointed out that the moving-coil ammeter customarily employed only indicates the mean current and not the maximum current through an X-ray tube excited by a pulsating voltage. It is concluded that while the moving-coil ammeter is adequate for the measurement of sustained tube currents, it is best to use some form of ballistic meter for currents lasting less than about a second.

Structure of Cellulose. One of the difficulties in correlating the physical and chemical properties of cellulose is the peculiar, almost self-contradictory, nature of this substance. Thus, the tensile strength of an artificial silk fibre may correspond weight for weight with that of a wire made from a light metal such as duralumin, although so far as transparency and conductivity of electricity and heat are concerned, cellulose has no semblance of metallic properties. A combination of X-ray and chemical methods will probably ultimately provide the explanation of these difficulties, and it is from this point of view that Prof. M. J. Duclaux describes the results of recent work on the subject in *La Papeterie* (Nos. 18 and 19; 1932). The X-ray diagrams are best explained on the assumption that the greatest length of the cellobiose molecule is equal to that of the crystal lattice (10·3 A.). This, in fact, is the foundation of the theory proposed by Mark and Meyer, namely, that the lattice takes the form of an oblique prism, and it involves the orientation of a cellobiose molecule at each corner and one joining the horizontal faces; two such molecules would then be common to each of four continuous lattices. Opposed to this is Staudinger's suggestion that the cellobiose molecules may form a long chain, and this is supported by the progressively increasing viscosity and decreasing solubility of chain complexes built up from simple molecules. One is left with the impression that the arguments in favour of each type of structure are equally potent, but that once the question of the length of the chains is settled a big step will have been taken in the direction of a solution of the problem.

Astronomical Topics

Occultation of Regulus on April 6. Extensive preparations were made to observe this occultation at stations near the northern boundary, which crossed England from Liverpool to Dover. Both in the neighbourhood of Canterbury and in that of Hitchin, parties of astronomers occupied posts about a mile apart along lines at right angles to the boundary: but clouds prevented any useful results from being obtained. The only time-observation to hand was made by Rev. O. Walkey at St. Buryan, Cornwall; long. 5° 36′ 18″ W., lat. 50° 4′ 58″ N.; in a letter to the *Morning Post* he gave the time of disappearance as $20^{h}35^{m}23^{s}$ U.T., but did not give the time of reappearance, though he stated that the star was hidden for 45^{m}, which is the maximum for any point in the British Isles. The phenomenon was seen as a spectacle from Worthing, but no times were recorded. It is worth while to remind the public that they can do useful work by timing the disappearance of stars, using the wireless time-signals to find the errors and rates of their clocks. The times must be given to seconds, and the position of the station determined from a large-scale ordnance map.

A Remarkable Short-Lived Nova. A photograph taken at Uccle by MM. Delporte and Arend on the evening of March 20 showed an image of a star of magnitude 13·2 (the first announcement gave mag. 11·0, but this was corrected to 13·2) of which no trace could be seen on earlier plates, one of which was taken in 1927, four in 1932 and one on March 18, 1933; this last showed stars to mag. 17·0. The position of the star for 1933.0 is $7^{h}18^{m}29·13^{s}$, N. 28° 38′ 1·7″. The following further observations were made at Uccle on the evenings of the dates named: March 21, mag. 13·5; March 22, mag. 14·5; March 23, mag. 17·0; on March 24 it was invisible, but the observing conditions were bad (U.A.I. Circs. 430, 431, 432). Further information is contained in Harvard Cards 264 and 265; the star was not found on Harvard plates taken on March 17 and March 22, which show stars to mag. 12; but plates taken by Prof. G. van Biesbroeck with the 24-inch reflector at Yerkes show it of mag. 14·5 on March 23·17 U.T., and of mag. 16·5 on March 24·19 U.T. The rapid rise and fall is thus confirmed. The star would seem to belong to a different category from ordinary novæ; also long-period variables generally remain at maximum for several days. The region should be scrutinised from time to time in case of a reappearance.

Report of the Director of Leyden Observatory for 1932. This report gives evidence of a large amount of valuable work carried out not only at Leyden but also at Johannesburg, at an equatorial station in Kenya, and at the Perkins Observatory in Ohio. At the latter station Dr. Oort received permission to take a number of plates of extragalactic nebulæ with the new 69-inch reflector; these are to study the surface luminosity and the distribution of light in different portions. The observers at the Perkins Observatory have promised to continue the series; the plates will be measured at Leyden. The work of Dr. Hins and Mr. van Herk in Kenya is nearly completed. Its object is to obtain fundamental declinations by observations of the azimuths of stars when they are moving vertically in the east and west. The results should be free from the uncertainty due to refraction. The time spent at the station was too short to give a complete catalogue of fundamental declinations; all that was aimed at was to give a full test to the possibilities of the method, in the hope that it may be carried out on a larger scale.

Plates for the determination of proper motions in the Pleiades continue to be taken under the direction of Prof. Hertzsprung; Mr. Uitterdijk examined the proper motion of the star 190 in the cluster N.G.C. 1647; it was suspected that this was a white dwarf accidentally superposed on the cluster, but the observations show no appreciable relative motion, so that it belongs to the cluster and is not a dwarf.

Several members of the staff went to America for last year's solar eclipse and the meeting of the International Astronomical Union at Harvard; Prof. Hertzsprung took advantage of his visit to Harvard to obtain estimates of the magnitude of variable stars from the immense series of plates that are now rendered easy of access by the new buildings erected for them. A 16-inch equatorial is being constructed for the observatory by the firm of Sir Howard Grubb, Parsons and Co. This will be erected in the grounds of the Union Observatory, Johannesburg, by kind permission of the latter, which has for many years been carrying on a scheme of joint work with Leyden.

Botany in Russia

NUMBERS 1–5 of vol. 27 of the *Bulletin of Applied Botany, of Genetics and Plant Breeding*, issued at Leningrad, 1931, under the editorship of Prof. Vavilov, director of the Institute of Applied Botany, present a most impressive picture of the vigorous research along purely scientific lines, as well as into applied problems, which is proceeding in the U.S.S.R. In all, these five numbers contain more than two thousand pages. The papers are in Russian but are generally accompanied by English abstracts, upon which the following notes are based.

In the first number, G. A. Lewitsky summarises the work carried out in the cytological laboratory of the Institute of Plant Industry in the period 1927–30. The investigations have been governed by no less ambitious an aim than the discovery of the variations undergone by the nucleus during the process of evolution. This obviously involves studies linking cytology with systematics, and the work began with the genus *Festuca*. Here it was found that the polyploid multiplication, now so well known to the cytologist, penetrated into even the last subdivisions of the genus made by the systematist. The work then spread to the karyology of the whole great family of the Gramineæ, on which a monograph by N. P. Avdulov is now being published. This work has revealed another type of chromosome variation, affecting the individual units of the haploid group. In the Gramineæ, it is concluded, the basic number of chromosomes has diminished with evolution, from 12 and 10 in primitive types to 7 and 5 in more specialised stocks; along with this has proceeded a change from the tiny dumb-bell shaped chromosomes of the Oryzeæ and Panicoideæ to the larger worm-shaped chromosomes of the Poæoideæ.

Such researches necessitated the elaboration of methods of elucidating the morphology of the chromosomes, and the present volume consists largely of papers describing the methods thus developed and the results obtained. The relation of chromosome morphology to systematic affinity is elucidated in an intensive study of the sub-family Helleboreæ. A paper is also included upon the alterations induced in the chromosome by X-rays. The whole volume describes an intensive study upon fundamental cytological problems and it is to be hoped the results may be rendered more accessible to non-Russian workers.

No. 2 contains several important papers upon cereal breeding and upon genetical studies with other economic crops; in particular, British cereal breeders will be interested in the studies of A. A. Orlov on the collection of barleys in the Institute of Plant Industry and of V. V. Suvorov on the Russian barleys. Orlov concludes that the barleys of Abyssinia and Eritrea are at the present time in a stage of an "impetuous creative process"; a re-arrangement of hereditary characters is proceeding actively and a number of new forms originating. Barleys are thus turning up which are very important from an agronomical point of view and have great biological plasticity.

Papers are also included upon the baking properties of mixtures of wheats and upon the connexion between physical and chemical characteristics of the wheat grain and the yield of flour. V. M. Kalashnikov has a paper upon breeding experiments with 'guayule' (*Parthenium argentatum* Gray) which is apparently to be tried in Russia as a home-grown source of rubber.

No. 3 contains more than 650 pages upon the forest studies and work on forest products carried out under the guidance of E. E. Kern. These studies of the possibilities of native trees and the behaviour of introduced species have naturally great interest for foresters.

No. 4 contains a more miscellaneous series of papers arising out of Russian genetical studies. T. Asseyeva continues her important studies of bud mutations in the potato. She has now more than 150 mutants under study and concludes that in an overwhelming majority of cases they show the structure of periclinal chimæras.

Percival had suggested that the number of veins in the coleoptile might have systematic value (*Ann. Bot.*, 41, 1927) and M. S. Jakovlev and E. I. Nikolaenko have tested this character over a much wider range of wheats. It appears to have systematic value but to lead to conclusions different from those drawn by Percival, especially in connexion with the Abyssinian wheats. Studies upon rice and upon the durum wheats of the northern Caucasus are also included in this part.

No. 5 contains the results of investigations carried out in the physiological laboratory of the Institute of Plant Industry under the general direction of N. A. Maximov. Naturally, therefore, studies on photo-periodism and upon water relations predominate. V. Rasumov has an interesting paper upon the effects of altering length of day upon tuber formation in a number of races of *Solanum* which had been collected by the Institute in an expedition to South America. Tuber formation in *S. tuberosum* seems to be unaffected by day length, but in several other species a delay is induced by exposure to a longer day.

Jrene Borodin has studied the inter-action of important mineral nutrients upon the reaction of barley and millet to changes in length of day; nitrogen deficiency affects this reaction in barley in an opposite manner to phosphorus or potassium deficiency. The work points to the conclusion that the carbohydrate-nitrogen ratio is not the immediate cause of the change from the vegetative to the reproductive phase but an associated phenomenon. The same conclusion is suggested by V. Rasumov's study of the localisation of photo-periodic effect, which suggests, like similar American work, a direct effect of the period of illumination upon the growing centres.

Sophie Tageeva has an interesting study of photosynthesis under long and short day conditions, which leads to the conclusion that this process proceeds at about the same rate in the plant, however long the period of illumination. On the other hand, a 'long day' plant, like oats, shows under short day conditions a considerably greater accumulation of substance than with a long day, an accumulation which must now be explained otherwise than by a more efficient photosynthetic activity.

Th. V. Bystrikov has a very interesting study of the root system of competing cultivated plants, in which what are defined as secondary crops oust primary crop plants, like wheat, flax, etc., because of a more rapid development of aerial parts and a profuse branching of a more vigorous root system. He states that, in opposition to the views of the textbooks, the primary roots of the cereals do not die off early but remain intact and vital until the beginning of harvest.

Mme. Krasnosselsky-Maximov has attempted to elucidate the internal causes delaying reproduction in the winter forms of cereals. She is led to the conclusion that the winter forms contain a substance, possibly a hormone, which causes delay in reproduction.

The specific nature of the studies on moisture relations can only be briefly indicated. Ivan Vasiljev has a study of the influence of drought upon carbohydrate transformations in wheats. As usual, hydrolysis is increased with desiccation and synthesis with improvement in the water supply. J. N. Kondo has studied the influence of external, as well as internal, developmental factors, upon resistance to drought, whilst S. Kolotov examines the influence of soil moisture as a growth factor, and S. M. Ivanov attempts to determine the frost resistance of plants by changes in the electrical conductivity of the sap induced by frost injury.

Priestley Celebration at the Chemical Society

PRIESTLEY commemoration discourses were delivered before the Chemical Society on April 6 by Sir Philip Hartog, Prof. A. N. Meldrum, and Sir Harold Hartley, and there was also an exhibition of manuscripts, portraits, medals, books, apparatus, and personal mementoes lent by the Royal Society, Dr. Alexander Scott, Mr. G. H. Gabb, Mrs. Arundell Esdaile, Mr. W. C. Priestley, Dr. C. H. Spiers, and Dr. J. A. Newton Friend, or in the possession of the Chemical Society. Unfortunately, few of Priestley's instruments survive, as nearly all of them, together with his books and manuscripts, were destroyed when rioters sacked his house at Farhill, Birmingham, in 1791.

Sir Philip Hartog dealt particularly with Priestley's own peculiar personality and history as a scientific man and theorist, and said that in some ways he had been singularly misjudged. Priestley had an amazing facility for mastering different subjects. He published some fifty works on theology, thirteen on education and history, about eighteen on political, social, and metaphysical subjects, and twelve books and some fifty papers dealing with physics, chemistry, and animal and vegetable physiology. He also knew Latin, Greek, French, German, Italian, Hebrew, Chaldee, Syrian, and began Arabic. The main purpose of his life was one of religion and piety ; his love of science, which he regarded as a relaxation, became obvious at a very early stage. He was the pioneer of the introduction of the teaching of science in schools.

Priestley had a clear vision of the value of hypothesis in scientific investigation, and repeatedly expressed his views on the relation of speculation to facts. Sir Philip Hartog examined and totally rejected the familiar statement that Priestley was 'unable to grasp' the new ideas of the composition of water, showing that he was at one time a convert to those ideas, that his attitude was based on his experimental observations, and that he declared himself ready to be influenced by any new and stronger evidence. Sir Philip Hartog summarised his brief appreciation of Priestley's personal qualities in the words : "Priestley was a glory not only of British science, but of British manhood".

Prof. Meldrum divided his discourse into two parts, showing in the first that Priestley, by his work on gases, made a contribution to science that is unique, and in the second exhibiting his work on nitrogen peroxide. He began by examining two problems which arose in the seventeenth century and were pursued in the eighteenth century by Hales, Black, and Cavendish : the absorption and production of air in general, and the existence of gases distinct from air and from one another. Priestley, who owed much to Cavendish, was self-trained in experimental science ; he made the remarkable admission that his knowledge of chemistry was poor and that he was "not a practical chemist". Chemistry, up to his day, had been concerned so much with solids and liquids that its learning and processes were of little avail in work upon strange gases. Priestley was unique in being the first to handle gases boldly, easily, and quickly. Discussing what is meant by the 'discovery' of a substance, Prof. Meldrum said that Priestley got no credit for the discovery of nitrogen peroxide. He then gave an account of Priestley's preparation of nitric acid, his experiments on nitric oxide and nitrogen peroxide, and his production of nitro-sulphuric acid. The work showed his ardour for discovery, the resources of his mind, and his clever hands that nothing could escape.

Sir Harold Hartley said that Priestley's great service to chemistry was the extensiveness of his work, which revealed to chemists the variety of substances which could exist in the gaseous state, their individuality, and the importance of the part they played in chemical reactions. Priestley often ascribed his discoveries to chance, but in this he was unfair to himself, as he had a real genius for taking advantage of the opportunities that fortune offered him, and many of his researches showed that he could follow up a clue with a fine logical piece of investigation. Sir Harold Hartley described some of Priestley's work in connexion with the composition of the atmosphere, with the analysis of air, and with the practical applications of his discovery of oxygen. Priestley determined the relative density of gases, examined the combination of gases by volume, used solubility determinations as a means of identification, measured coefficients of thermal expansion and the conductivity of sound in gases, compared thermal conductivities, made the first experiments on gaseous diffusion, performed experiments with electricity, and was the first photo-chemist.

The secret of Priestley's genius as an investigator was his enthusiastic energy and curiosity, his fertility of mind, the ingenuity and enterprise with which he devised new experiments with the simplest means, his keen observation, his exceptional visual memory, and the rapidity with which he could develop a new investigation. There was behind everything the impelling force of his love for science, his devotion to experiment, and his boundless faith in the possibilities of new scientific discoveries. Dante's phrase well described Priestley's eager restless spirit, fearless and untiring in the defence of liberty and in the quest of truth : "con l'ali snelle . . . del gran disio".

Origin of the Chile Saltpetre

In the *Chemiker-Zeitung* of February 18, Dr. C. T. Kautter describes some observations which he has made of climatic conditions in Chile, which he believes may throw an interesting light upon the origin of the saltpetre deposits.

In 1924, Prof. Stoklasa suggested that the formation of these beds might be due to a combination of volcanic and bacterial action, the latter being catalysed by radioactivity. In support of his views he investigated a series of samples of caliche in which he was able to determine the existence of 80×10^{-12} gm. radium per gram of mineral. That not only the deposits themselves but also the overlying atmosphere should exhibit radioactivity appears to Kautter to be probable though unimportant. He brings forward the suggestion that the formation of nitrates can be explained by well-known physico-chemical changes which are independent of radioactivity.

The district of northern Chile in which the nitrate is found is undoubtedly volcanic in character and the vastness of the deposits and the absence of characteristic fossils have led to the abandonment of the idea that the caliche is of animal or vegetable origin. The violent thunderstorms which occur with great frequency in the high mountains in the summer are accompanied by discharges at such high potentials that the conditions for the production of nitric oxide are most probably fulfilled. Further oxidation of this gas to nitric acid and its subsequent action upon the common salt which is abundantly supplied by volcanic action would lead to the formation of sodium nitrate, but the transference of the latter to the nitrate zone, some hundred kilometres farther westward, is not so easy to comprehend, for the geological evidence seems to be against the idea of transference by sedimentation.

Now it has perhaps not been sufficiently well recognised that the nitrate zone, which extends about 100 km. inland from the coast and lies between lat. 19° and 26° S., is particularly subject to the visitation of immense cloud-banks of fog, which rise almost vertically to a height of about 1,000 m. against the coastal heights before being carried inland. Close observation has shown that these banks of cloud operate only within a limited and fairly well-defined area, with its centre at the coast and extending to the prairies or pampas, which lie at distances varying from 30 km. to 80 km. from the coast-line. It is significant that the greatest accumulation of cloud is to be found overlying the zone which is richest in caliche. Now these thick clouds, which often hang for long periods over the nitrate zones, may serve as transporters and condensers of the oxides of nitrogen which are formed by the frequent electric discharges. It is also suggested that nitrogen may become activated during the evaporation of the water, though this has not been experimentally verified.

Good deposits of caliche are frequently found not only in the valleys or plains but also at overhanging cliffs on the mountain-sides, wherever any resistance to the flow of the cloud may be offered. These arrested portions of cloud are eventually dispersed by the sun, when the nitric acid is deposited. Further confirmation of this theory is to be found in the fact that isolated deposits of caliche can be traced to the breaking away in certain areas of patches of cloud which drift away from the main areas of concentration.

Thus the deposits of nitrate are formed by the gradual evaporation of the clouds in the enormous basins in the mountainous regions. Even the relatively high concentration of iodine in the caliche, which has sometimes been quoted as evidence in favour of its production from organic remains, can be satisfactorily accounted for on this theory. The iodine content of the air is particularly great at the sea-level. It is stabilised by oxidation by ozone and nitrogen peroxide to iodic acid. Thus the author draws the interesting conclusion that in this case Nature adopts much the same process as that in operation in modern technology, namely, the combined action of water, air, heat and electricity.

Ecology of the Lucerne 'Flea'

The so-called lucerne 'flea', *Smynthurus viridis*, is an insect of the spring-tail group (order Collembola) which is widely spread in Europe. It also occurs in the southern hemisphere, where it has most probably been introduced and, in South Australia, it has become a major pest of lucerne. It is a common insect in Britain and, taking advantage of this fact, Mr. D. Stewart Maclagan has made an extensive study of the rôle of environmental factors in relation to the normal natural increase of the *Smynthurus* population.

Under the title of "An Ecological Study of the Lucerne 'Flea' ", Mr. Maclagan has published (*Bull. Entom. Res.*, **23**, 101–145 and 151–190; 1932) observations carried out, in the main, at the Imperial Institute of Entomology Laboratory at Farnham Royal (Bucks). It is not possible to enter into a detailed consideration of the many important points that are discussed by Mr. Maclagan. In addition to studying the bionomics of the insect, and the effects of predators and parasites upon its survival, a critical analysis of the part played by the physical environment is also presented. The influence of temperature, humidity and soil pH values upon growth, fecundity, and longevity are very fully explored and a general estimate of these combined environmental effects is given. While the first paper is devoted largely to experimental laboratory studies, the second contribution is concerned in the main with the analysis of field data, and the two lines of approach are discussed in conjunction by the author in his conclusions. The value of climatological studies, when checked and analysed by laboratory experimentation, is considered with special reference to the prediction of the possible geographical range of the insect.

The author concludes that the analysis of the complex of environmental factors is an essential preliminary to the study of biological methods of control. The physical environment, he claims, assumes the major rôle in the control of insect populations since it exercises a profound influence on predators, parasites, and hosts alike, resulting in a maze of often unsuspected relationships. Mr. Maclagan's papers form an important contribution to the exact study of animal ecology and are to be commended to the notice of all students of the subject.

University and Educational Intelligence

LIVERPOOL.—Through the gift of Mr. William Horton, the Science Library has gratefully received a sum of money, to be expended over a period of seven years, towards the maintenance of science journals.

The Senate and Council have resolved to confer honorary degrees at the summer graduation on the following: Mr. Stephen Gaselee, librarian and keeper of the papers at the Foreign Office, Miss Eleanor Constance Lodge, until recently principal of Westfield College, London, Prof. G. I. Taylor, Yarrow research professor of the Royal Society, Sir J. Eric Drummond, secretary general of the League of Nations, Mr. R. D. Holt, chairman of the Mersey Dock and Harbour Board, Mr. F. W. H. Groom, until recently head of the Liverpool Institute, the Rev. Father Joseph Howard of Liverpool, Miss D. C. Keeling, secretary of the Liverpool Personal Service Society, and Mr. Percy J. Robinson, chief electrical engineer of the City of Liverpool.

HUDDERSFIELD TECHNICAL COLLEGE has been able to report a record attendance of students during the past academic year, the increase in the number of day students (461) being specially marked. The volume of work has increased by 121 per cent since 1920, when a new Textile Department was opened. Among other developments reported by the Principal are the formation of additional practical classes to meet the extraordinary demand for instruction in smoke abatement and fuel economy and provision for helping unemployed adult engineers by reserving the workshop at certain times for fitters, turners and machinists who wished to practise their trade and to use machines of which they had had no previous experience.

MEXICO'S new rural schools, known as "Houses of the People", are described in Bulletin No. 11 of 1932 of the United States Office of Education, a brief summary of which appears in the November issue of *School Life*. They are the product of a bold scheme designed to build a new civilisation incorporating a revival of the best features of indigenous culture—Mayan, Toltec and Aztec as well as that of the Spanish conquistadors. The federal government selects and pays the teachers and buys the books, but the local community provides the building and equipment and guarantees an ample attendance of both children and adults. As soon as the teacher has been selected, the building of the school is begun, the labour being provided by the community, men, women, and children, working under the direction of the teacher and using materials (adobe brick) obtained locally. Classes are conducted meanwhile in the open air. Courses are not prescribed by the central authorities but the teacher who lives in and knows the community is left to initiate projects of education adapted to local needs. Health, including dietetics, is a basic school subject and the teacher undertakes such simple medical service as vaccination and dispensing remedies for common complaints. The school garden and playground are regarded as indispensable adjuncts. How Mexico finds teachers competent to perform the varied tasks demanded of them is not explained. Hitherto an enthusiastic belief, on the part of teachers and taught, in the value of the scheme appears to have overcome all obstacles to its success.

Calendar of Nature Topics

The Ice Bridge

The Great Lakes of America and the waterways of the St. Lawrence and its estuary are firmly frozen over every winter. The ice begins to break up towards the end of March, and from the middle of April to the middle of May large quantities of drift ice are swept down into the Gulf of St. Lawrence. The opening of this Gulf is almost entirely blocked by Newfoundland and Cape Breton Island, and nearly every year the gap between these islands is completely filled by great masses of ice. This block sometimes lasts for three weeks; it completely prevents the passage of ships, and is known as 'the Bridge'. As many as 300 ships have been held up at one time, and the Bridge is the cause of frequent wrecks on the coast of Newfoundland.

Clover Mites Invade Dwelling Houses

Clover mites (*Bryobia prœtiosa*) live amongst grass and upon the twigs and foliage of many fruit trees. In late autumn the females deposit eggs which hatch in spring, and during April the newly hatched individuals have been known to invade dwelling houses in enormous numbers. In such a case investigated by the writer in 1929, the mites appeared on the outer wall of a house near Edinburgh, on the window sills, and within the house upon the woodwork of the window and shutters, in such numbers that although each mite is less than a millimetre in length, their presence attracted the notice of the householder and was regarded by her as disturbing and troublesome (*Scot. Nat.*, 1929, p. 126). The house was recently built and the explanation of the invasion was that close to it was a grass plot, part of the original pasture field in which the site had been chosen. The invasion lasted several weeks, but the thorough spraying of the grass plot with an insecticide put an end to the plague. In the United States there are records of large numbers of clover mites invading houses, but there the invasions have taken place in the autumn.

The Lambing Season in Great Britain

The peak of the lambing season occurs in spring and indeed it is one of the accepted signs of spring for general observers. Watching the young lambs in field or fold, we may not realise that a farming enterprise of some uncertainty is in progress, in which success or failure depends on a high degree of skill on one hand and much applied science on the other. It is a case of the economical production of an article intended for a discriminating market. The first problem is the choice of suitable breeds of both ram and ewe, and this in itself is no simple matter. In a recent survey of the south-west counties of Great Britain, it was found that no less than 82 distinct crosses were in use. Prolificacy and hardiness in the ewe, with early maturity and quality in the offspring, are the main points looked for, and thus an exacting standard is set up.

The first few weeks of life present many dangers both to mother and offspring, and even under good management serious losses are not uncommon. When this critical stage has been passed a keen watch for disease must still be kept. Veterinary science has already done much to mitigate the effect of internal parasites and foot rot (a virus disease), but there are still obscure troubles, mostly associated with land which has been overstocked with sheep, that cause much unthriftiness and loss.

Knowledge is being sought in two directions. The scientific study of well-recognised problems of nutrition or disease: and the sifting of the very large body of experience which at present exists in an unavailable form in the minds of keen observers—the flockmasters and shepherds themselves. The partnership should turn out to be a very helpful one: the practical man with a highly developed live-stock sense bringing his problems to the scientific expert, and perhaps from his empirical knowledge providing some useful clues for their solution.

Breeding Haunts of the Harp Seal

When the 'fishing' of the whalebone whales in the North Atlantic came to an end, and the whalers from British ports turned to sealing, it was reckoned a lucky day if the ship struck a breeding place of the harp seal (*Phoca grœnlandica*) in the early part of April, for then the crew would be able to slaughter as many as the ship could hold. The reason was that the harp seal is gregarious and in those days was also exceedingly numerous, so that, as Dr. R. W. Gray has quoted from a description written in 1870 by his father, a great whaling and sealing skipper, "fifteen or twenty years ago a pack of [breeding] seals extended in every direction as far as could be seen with a good telescope from a ship's masthead, lying as close as a flock of sheep"; or as Gravill, a Hull whaler and sealer, said, "I've seen them in Greenland [meaning the Greenland Sea] extending on the pack [ice] for a distance of twenty or thirty miles, young ones and old, just a solid body of seals". (*Naturalist*, 1932, p. 183.) The reason why every sealing ship did not return laden when such plenty existed, was that the breeding places were not fixed, their position depending upon the ice conditions and food supply in the Greenland Sea. The harp seal, so named because of the shape of the curious dark line which seems to be stamped on the white coat of the adult, breeds upon the margin of the arctic ice, where it is breaking up into pack ice, for there the seals have at the same time support for their young and the possibility of abundant food in the sea about the ice-floes.

Food of the Harp Seal and its Significance

Harp seals feed upon the small crustaceans in the plankton of northern seas. Dr. R. W. Gray found them to contain *Euthemisto libellula* and *Nyctiphanes norvegica*; and if they also devour the fishes which live upon the plankton, none the less the distribution of the crustacean plankton is of vital significance. Here is a link which connected the whaling and sealing of the nineteenth century, for harp seals and whalebone whales take advantage of the same food supply, so that often enough the whales were captured amongst the floes upon which the seals were breeding. Dr. Gray has analysed, in the paper referred to above, the records contained in the log-books of certain of the Peterhead sealing ships from 1862 until 1891, and has tried to explain the distribution of the former breeding places in relation to the food supply.

The harp seals usually produce their single young in March in about lat. 73° N., north-east of Jan Mayen, where the ice forms a great easterly projecting point exposed to the swell of the ocean on three sides, termed by the old sealers 'the point or end of the sealing ice'. The very large numbers of seals demanded an enormous amount of crustacean plankton. The presence of such abundance, together with pack-ice suitable for the seals, determined the breeding place in lat. 73° north-east of Jan Mayen or in long. 12° W., west or south-west of that island. In years when the western waters were covered by solid ice, and so were locked up from the seals, the breeding place was confined to the eastern position; whereas if the eastern waters were entirely free from ice, and so for another reason were unsuitable for breeding seals, the herds moved to the localities west or south-west of Jan Mayen.

Societies and Academies

London

Physical Society, Feb. 17. M. C. Marsh: The transmission of heat through fabrics. The results obtained in earlier papers have been analysed to determine the effects of air permeability and of perforations on the thermal insulating properties of fabrics. It is also shown that there is a heat-interchange between the convection currents and the fabric which is important in considering the flow of heat through such insulators. L. F. Bates and B. J. Lloyd Evans. A compact electromagnet for general purposes. Special attention has been paid to the construction of the coils, which are cooled by the circulation of oil. J. V. Hughes: On the spurious ring exhibited by fluorescent screens. The spurious ring exhibited by fluorescent screens used for the observation of electrons is explained as being due to total internal reflection of the light at the upper surface of the glass block of the screen. The theoretical intensity-distribution is deduced and is compared with experiment by the use of a specially designed photometer. N. Thomson: The direct recording of relative intensities by means of a microphotometer. An addition to the usual form of recording microphotometer, giving a record on which ordinates are linearly proportional to light-intensities.

Geological Society, Feb. 22. T. E. Longfield: Subsidence of London. This subsidence has been confirmed by a recent, and still continuing, re-levelling of London. The principal lines of levels in this area have been completed and it was primarily from these that the deductions have been made. A comparatively new method is described by which levels can be transferred across water up to a distance of about a mile; this method has enabled the levelling network to be connected with accuracy across the estuary of the Thames at Dagenham and Tilbury. Evidence of (1) a more or less general sinking in the area of the south-eastern counties, and (2) a fairly general subsidence in the Metropolitan area has been obtained. As regards general sinking, the observations showed that the land surface at Felixstowe is lower relatively to mean sea-level by 0·17 ft. than it was fifteen years ago, and if this scale is maintained it would give a subsidence of 1·2 ft. per century, a figure which is of the same order as that arrived at by the estimated lowering of the Neolithic deposits and Roman remains in the Thames Valley, which were respectively 60–70 ft. and 12–15 ft. below mean sea-level. If the results of the first geographical levelling of Great Britain are taken at their face value, these also suggest a lowering of the south-eastern counties by 1–2 ft.

since 1850. A fairly general subsidence has been found in the Metropolitan area; it appears to commence in each case where the London Clay gives place at the surface to gravel, and reaches local maxima in areas of alluvium and over such erstwhile rivers as the Tyburn and the Wall-brook. The draining of water from the gravels is suggested as the cause of this subsidence.

Paris

Academy of Sciences, Feb. 27 (*C.R.*, 196, 581–652). The president announced the death of Johannes Schmidt, *Correspondant* for the Section of Anatomy and Zoology. Elie Cartan: The spaces of Finsler. A. Cotton: The construction of thermoelectric elements. The suggestion of A. Egal regarding the construction of thermoelectric elements had been anticipated by Wilson and Epps in 1920. Charles Nicolle and J. Laigret: The extension of the immunising power of exanthematic viruses by combining the action of two viruses of different origin. C. Gutton and Mlle. M. Chenot: The propagation of electrical oscillations along a tube containing an ionised gas. E. J. Gumbel: The meaning of the constants in the Gompertz-Makeham formula. Alfred Rosenblatt: Some theorems of the theory of ordinary non-linear differential equations of the second order. Georges Giraud: The validity of Fredholm's theory for certain non-limited nuclei. A. Marchaud: The criteria of unicity and of multiplicity by integrals of a system of differential equations of the first order. Eugène Blanc: A differential property of the *continus* of Jordan. E. Crausse and J. Baubiac: Transitory regimes. Experimental study of the transition regime corresponding to setting a viscous liquid in motion starting from rest. Reynolds's law of similitude applies to all the cases studied. Henri Mémery: A remarkable epoch of solar activity (first fortnight in February). From the data available (1880–1933) the author deduces that the sunspots show a tendency to accumulate at certain dates, about the first fortnight in February. Ernest Esclangon: Remarks on the preceding communication. The conclusions in the preceding paper must be accepted with reserve since it would lead to the surprising conclusion that there is a connexion between the production of sunspots and the period of revolution of the earth round the sun, a connexion which logically must be extended to the other planets. E. Prévot: The influence of the daily oscillations of the vertical on the results of high precision levelling. *Attention is directed to the possible consequences of the thermal oscillation of the vertical upon exact geodesic measurements.* J. Solomon: The theory of the diffusion of neutrons. Jean Jaffray: The high-frequency currents produced by high-tension magnetos. If the spark gap is short-circuited, high-frequency currents are still produced; the frequency is independent of the velocity of rotation of the magneto. Nicolas Perakis and Léandre Capatos: The constant paramagnetism of metallic rhenium. Over the temperature interval +20° C. to –79° C., rhenium possesses a paramagnetism independent of the temperature: the coefficient of magnetisation found was about eight times that found by Albrecht and Wedekind. The difference does not appear to be due to impurities. René Wurmser and Mme. Nélicia Mayer-Reich: The equilibrium between lactic and pyruvic acids. Pierre Achalme: The chemical nature of the neutron. If it is assumed that the absolute value of the charge of the negative electron is double that of the positive charge of the proton, an assumption which is in contradiction with no known experimental fact, then the neutron would be formed by the intimate union of two protons and an electron, and would have an atomic weight 2. The author adduces some experimental evidence in support of this view in connexion with the allotropic states of hydrogen. Maurice Nicloux: The oxidation of sodium hydrosulphite by free oxygen. The author's experiments are consistent with the reaction

$$Na_2S_2O_4+O_2+H_2O=NaHSO_3+NaHSO_4.$$

Emile André and Armand Bloch: The presence of ether-esters of glycerol in various elasmobranch liver oils and some analytical characters peculiar to these oils. Marcel Godchot and Max Mousseron: Two methylamino-cyclohexanols and their resolution into their optical antipodes. L. Palfray, S. Sabetay and Mlle. Denise Sontag: The potash dehydration of the β-phenylethyl alcohols halogenated in the nucleus. The halogen styrolenes. Pierre Bedos and Adrien Ruyer: The oxide and polyalcohol derivatives of 1·3-cyclohexadiene. Mlle. Simonne Caillère: Study of the thermal dissociation of the serpentine minerals. P. Fastré: The measurement of the reflective powers of some natural tellurides by the photoelectric method. Fernand Blanchet: The age of the Guillestre marbles, a rock characteristic of the Malm of the *Briançonnais*. Paul Bertrand: The specification of the *Cladoxylon* and *Clepsydropsis* of Saalfeld. Raymond-Hamet: The botanical origin of the drug known under the name of *Muira Puama*. R. Gautheret: Cultures of cells detached from the root cap. Laurent Raybaud: The advantages of germinated grain for feeding farm animals, especially the horse. M. Aron and J. Comsia: Experimental researches on the rôle of functional stimulation in the development of the digestive apparatus in the larvæ of *Rana*. Emile Haas: The accommodation effort of corrected ametropes. Jean Roche and Pierre Dubouloz: Study of the constitution of the hæmocyanins and hæmerythrins by means of their ultra-violet spectra. F. Pasteur: High-tension galvanic electrotherapy.

Rome

Royal National Academy of the Lincei, Dec. 4. F. Enriques: (1) Certain invariant series of groups of points on an algebraic surface. *As an extension of Severi's investigation of rational series of groups of equivalent points on a surface, the construction of an invariant series of groups of points having absolute invariance is considered.* (2) Arithmetic irrationalities occurring in the plane representation of the rational surface with elliptical sections of the eighth order. U. Cisotti: Translo-circulatory current in presence of a circular obstacle furnished with an indefinite rectilinear appendix. Q. Majorana: A new photoelectric phenomenon exhibited by metallic sheets. The increase in the electrical resistance of thin sheet metal under the influence of light is confirmed, and the experimental results previously described modified slightly. Thus silver, although it displays selective sensitivity towards wave-lengths of less than 3000 A., is still sensitive to higher wave-lengths. Further, all the other metals tried, with the exception of aluminium, are distinctly sensitive to ultra-violet light. Various means are available for distinguishing between this effect and the thermal variation of the resistance. G. QUAGLIARIELLO: The presence, in the cells of adipose tissue, of a dehydrogenase acting on higher fatty acids. An enzyme, with an action similar to that of the enzyme recently detected in bile, occurs in adipose tissue. A. COMESSATTI: The canonical series of an algebraic surface. F. TRICOMI: A transcendent equation of statics. M. KOURENSKY: The integration of the equations to partial derivatives of the second order with two functions of two independent variables. (3) Systems containing four derivatives of the second order. R. ZOJA: Distribution of the internal tensions in a solid with rectilinear axis and rectangular transverse section. Uniform distribution of the tangential tension (5). M. BOSSOLASCO: Magnetic measurements at Mogadiscio. Measurements of the magnetic elements during August and September, 1932, show that the secular magnetic variations at Mogadiscio have continued during the past six years, but appreciably more slowly than previously. O. BOTTINI: Relationships between the chemical composition of the soil and that of its colloidal contents. Treatment of three alluvial soils free from lime, by washing with water and decantation, shows that, in such soils, chemical decomposition tends to lixiviation of the bases and silica and so leads to the accumulation of ferric oxide and alumina. Comparison of the elementary composition of the soil with that of its colloidal contents gives an indication concerning the degree to which the soil has undergone degradation: the greater the degradation, the more nearly do the two compositions approach equality.

VIENNA

Academy of Sciences, Dec. 1. ERICH TSCHERMAK: Petaloid formation of the calyx in *Phaseolus multiflorus*. The formation of a coloured, corolla-like calyx, previously observed with garden primulas and auriculas, *Soldanella pusilla*, *Cyclamen europæum*, etc., has now been found in three individual hybrids of *Phaseolus vulgaris* and *P. multiflorus*. ROBERT SCHWINNER: Geology of Eastern Styria: the rocks and their inter-relationships. The rocks occurring in this district, especially in the mountainous district between Foistritz and Lafnitz, are described.

Dec. 9. FRIEDRICH LECHNER: Vibrations of certain systems of valency forces with four mass-points. GUNTHER LOCK: Cannizzaro's reaction (2). In continuation of earlier work, further halogenated derivatives, especially chlorobromo-derivatives, of *m*–hydroxybenzaldehyde, have been subjected to Cannizzaro's reaction. The observation that this reaction occurs only with those derivatives which contain at least one hydrogen atom adjacent to the aldehyde group, is confirmed. KARL GIRKMANN: The calculation of cylindrical liquid-containers in relation to wind pressure. OTTO LICKENBERG: Geological and palæontological investigations in the northern Osterhorn group (Salzburg) (2).

Dec. 15. KARL PRZIBRAM: (1) Recrystallisation and coloration (3). The blue colour change of compressed, irradiated rock salt may be followed down to a loading of 100 kgm. per sq. cm. and a strain of about 2 per cent. The velocity of recrystallisation must be regarded as a function rather of the strain than of the pressure. The repression of the recrystallisation by irradiation previously observed has been confirmed by further experiments with specimens subjected to pressures of 10,000 kgm. (or more) per sq. cm. and also with potassium chloride and bromide; the last salt exhibits especially rapid recrystallisation. (2) Plasticity and hardness of crystals of alkali metal halides. The empirical plasticity law found earlier has been verified by numerous tests with sodium chloride and has been extended to potassium chloride and bromide. Measurement of the Brinell hardness of the three salts reveals, *inter alia*, strengthening by pressure and weakening by recrystallisation. HILMAR SCHUMANN: Petrographic phenomena in the Seckauer Tauern. FRIEDRICH KÜMEL: Outliers of the upper crystalline in the Rosalien Mountains. F. WERNER: New Greek Orthoptera from the region of the Aegean Sea. Observations during November at the Central Office for Meteorology and Geodynamics, Hohe Warte, Vienna.

Ethics and Archæology

In these days when public interest in science is growing—in itself an excellent thing, even though not universally regarded as an unmixed blessing—and calls for constant stimulation by accounts of the latest discovery, the problem of acknowledgment and the legitimate use which may be made of the results of recent research is one which in its general bearing affects all research workers in science and its practical and theoretical application.

Apart from the legal question of copyright, to plain straightforward people the rights of discovery at first sight are a simple matter. Credit must be given where credit is due. One rough and ready formula is that facts are free for use, but inference and theory must be attributed to their authors. This, however, is not universally applicable and in many instances is inadequate. In archæology and ethnology, both guidance and a safeguard are afforded by the nature of the material with which these studies deal. Unless a fact is so familiar as to have passed into the generally accepted currency of scientific data, as for example the discovery and determination of the character of Piltdown man, it must be authenticated before it is admissible as evidence. In the physical sciences, it is generally true that a statement of fact can be tested by the repetition of observation or experiment. The ethnologist and the archæologist must rely solely upon an observation which possibly may, but more often cannot, be repeated. When once an archæological site has been investigated by excavation, or an implement or other object has been moved from the exact spot on which it was found, its value as evidence has passed to the excavator's record. The conditions of discovery cannot be restored, and at best, assuming that the investigator is trustworthy and adequately qualified, the evidence as recorded can only be subjected to the test of internal consistency and congruence with the general body of scientific knowledge.

It is true that when the evidence of a material object is invoked, reference can be made to specimens in a museum or collection, as for example Sumerian gold ornaments or an Arunta churinga in the British Museum; but their evidential value in most contexts will be dependent on the fact that the former were found by Mr. C. L. Woolley in certain recorded levels at Ur in Mesopotamia and the latter was acquired by, let us say, Spencer and Gillen while it was actually in use among aborigines in Central Australia. Thus authentication and acknowledgment go hand in hand and are inseparable. In practice, any departure from this observance is unscientific, as well as lacking in a sense of obligation.

The Editor of *Antiquity*, in a recent issue of that journal, touched upon this point of ethics in archæology, referring to "the exploitation of other peoples' work before they have been able to exploit it for themselves" as a "Fleet Street pastime", and his comment was followed up by a correspondent, who asked for a ruling upon the length of time which should elapse before an exhibit in a museum may be considered available for the purposes of archæologists in general. The Editor of *Antiquity* having stated that he does not intend to discuss the matter further, we propose to offer some comments, dealing specifically with archæology and kindred studies.

As to how far it may be legitimate for an archæologist or ethnologist to make use, as material for his own work, of objects placed on exhibition in a public museum—naturally question does not arise in the same form in a museum in which the collections are privately owned—and whether there should be a 'closed time' for reference to such objects, the problem has been complicated by practices which have grown in recent years. In the ordinary course, it would be safe to say that any object which has been placed in a public collection and is open to the inspection of the public, is available for citation. If for any conceivable reason complete publication were not desirable, it would be within the discretion of the museum authorities; for presumably a photograph or accurate drawing would be an essential to such publication, and permission for access to the object for that purpose could be withheld.

This, however, affects only objects which come into the museum collections in the ordinary course; a more difficult question arises when a more or less extensive group of objects is shown as a collection of unitary interest. Owing to the growth of public interest in the expeditions of archæological exploration in which the museums, and especially the British Museum, now participate, such as that of Mr. Woolley at Ur, it has become a regular feature of the archæological year that the season's finds allotted to the Museum, and usually those allotted to other participants in the expedition while awaiting distribution, should be shown to the public for some weeks. This takes place before any report is sent to the excavator, and obviously places him at a disadvantage should he wish to make special use of any of the material, even if he were not busily occupied in clearing up the thousand and one loose ends after a season spent in the field.

The question of the use of the evidence afforded by the material objects thus exhibited, before the excavator has had time or opportunity to express his views concerning their bearing on the more general aspect of the problems upon which he is at work, is closely analogous to amplification or inferential treatment based upon either the isolated announcements of important discoveries or the periodical reports on work in the field, which it is now customary to send home for publication in the technical journals or even in the daily press. When archæological fields are so closely related in theoretical discussion and reconstruction as they are to-day, and students of prehistory are working along cognate lines of inquiry in which the evidence from one field may at any moment throw light upon the problems of another, it is difficult to draw any line beyond which it is fair to say there lies the exclusive field of original discovery.

Further, however nice the feeling which would err on the side of discretion rather than offend, there unquestionably must be a time limit. It is not every archæologist who is so prompt as Sir Flinders Petrie in the publication of the facts which have been brought to light by his excavation. Time and again, archæologists have had cause to deplore the delay in publication which has hampered research. Only recently in a notable archæological work, the author felt constrained to confine himself to one period only of his subject, and that not the most interesting, because the official report of the excavations in which he himself had participated was not yet published, although some years had elapsed.

There is another aspect of this question in which perhaps some relaxation of rule might be admitted. This is the popular exposition of the progress of discovery, however much this may be regarded as a "Fleet Street pastime". Any more extended understanding of the objects of archæological investigation among the more intelligent section of the public benefits the science in the long run. But to those who have no technical knowledge and whose acquaintance with even the barest outlines of knowledge of the prehistory of any specific area is of the sketchiest, the simple announcement of a discovery or even the account of the progress of an excavation is of little interest. It must be provided with a background, and it must be assigned to its place in some scheme of knowledge which is likely to be familiar to at least a fair proportion of its readers. Even so, it does not necessarily follow that the writer must be guilty of unjustifiable exploitation; but should that happen, the number of writers whose technical knowledge is sufficient to allow them to prejudice seriously the position of those who have first claim, is probably limited enough to ensure that punishment will follow and that it will fit the crime.

Modern Aspects of Chemistry in Space

Stereochemie: eine Zusammenfassung der Ergebnisse, Grundlagen und Probleme. Herausgegeben von K. Freudenberg. Lieferung 1. Pp. vi + 160. 18 gold marks. Lieferung 2. Pp. 161 – 320. 18 gold marks. Lieferung 3. Pp. 321 – 480. 18 gold marks. (Leipzig und Wien: Franz Deuticke, 1932.)

THE publication of an authoritative work on stereochemistry by a team of workers under the leadership of Prof. K. Freudenberg is a development which will be welcomed by many chemists. It is a sign of the times that an organic chemist should have secured the co-operation of so many workers outside his own field; and the thoroughness with which their co-operation has been sought and used is shown by the fact that Part I, dealing with aspects of the study of "Chemistry in Space" which have come into existence exclusively during the last two decades, includes chapters by Goldschmidt, Mark, Mecke, Wolf and Werner Kuhn, all of whom have in recent years been invited by the Faraday Society to take part in its general discussions, and are thus already well known to workers in Great Britain. It is therefore a very attractive scheme whereby each of these pioneer workers has been given an opportunity of providing an up-to-date report on the subjects in which he is specially interested.

These reports have, however, been written on the assumption that the organic chemists who read them are competent mathematicians, with an ample knowledge of physics, since no concession is made to the preference for chemical rather than mathematical equations and formulæ which sometimes decides the choice between organic and physical chemistry. The two subsequent parts, dealing respectively with the stereochemistry of carbon and of other elements, will include the topics which two successive generations have discussed under this title. The whole work is to be published in about eight instalments; but British chemists will be staggered when they receive a bill for considerably more than a pound sterling for an instalment of 160 pages.

(*a*) Prof. Goldschmidt's report on the "Crystallography and Stereochemistry of Inorganic Compounds" includes a study of atomic and ionic radii, on the lines of the author's lecture to the Faraday Society in 1929, but of much wider scope. As a contribution to a book on "Chemistry in Space", it is easy to follow, since the reader may be assumed to have acquired the habit of 'thinking in three dimensions', even if Einstein's fourth dimension is still beyond his powers of imagination. The numerous diagrams, in which the centres of the atoms are indicated by small well-spaced circles, are also clear and easy to understand, although the difference between the zinc oxide and zinc blende structures is not adequately explained in the text. The suggestion (on p. 70) that crystals of iron pyrites contain "the molecules S_2 which are already known in the gaseous state", is however perhaps ambiguous, since the reviewer has always regarded the twinning of the sulphur atoms as evidence that iron pyrites is a *ferrous disulphide*, $\overset{++}{\mathrm{Fe}}\,\overset{-}{\mathrm{S}}\text{–}\overset{-}{\mathrm{S}}$, containing a bivalent diatomic anion which may be compared with the peroxide ion in compounds such as $\overset{+}{\mathrm{Na}}\,\overset{-}{\mathrm{O}}\text{–}\overset{-}{\mathrm{O}}\,\overset{+}{\mathrm{Na}}$, or with the diatomic mercurous ion $\overset{+}{\mathrm{Hg}}\text{–}\overset{+}{\mathrm{Hg}}$ in mercurous nitrate. The report concludes by describing the fascinating work of W. L. Bragg on the silicates, of which an account has already been given in English in the new edition of the reviewer's "Inorganic Chemistry".

Two additional structures which might have been cited in detail are palladium monoxide, PdO, where each atom of palladium is surrounded by four coplanar atoms of oxygen at the corners of a *square*, whilst each atom of oxygen is surrounded by four atoms of palladium at the apices of a *tetrahedron*; and molybdenum and tungsten disulphides, MoS_2 and WS_2, where each atom of metal is surrounded by six atoms of sulphur at the corners of a *triangular pyramid* instead of the more familiar *octahedron*. These structures, which are illustrated by figures in a recent article by Maurice Huggins in *Chemical Reviews*, are so suggestive, as illustrations of the applications of X-ray analysis to stereochemical theory, that they might well be given a conspicuous place in a future edition of the present work.

(*b*) Prof. Mark's three contributions include an introductory report on "The Basis of X-Ray Analysis of Crystals", which does not call for special comment.

The second contribution, on "Interferometric Study of Molecular Form", supplements Prof. Goldschmidt's report, since it deals with the determination of interatomic distances in gaseous molecules by the diffraction of X-rays (Debye) and of electrons (Wierl), and with the application of X-ray analysis to solid organic compounds. A summary of the results obtained by the methods of Debye and of Mark and Wierl is very useful at the present stage, and their concordance is quite remarkable. Wierl's observations on pentane, hexane and 1:5-dichloropentane are particularly interesting in that the only spacings shown by the two hydrocarbons are 1·5 A. (between contiguous carbon atoms) and 2·5 A. (between alternate atoms), since these are unaffected by free rotation about the single bonds. The absence of a well-defined spacing between the two chlorine atoms of the pentane derivative confirms the conclusion that the hydrocarbon chain is not a stiff zigzag, although the mutual repulsion of the protons may suffice to impart a linear orientation to the hydrocarbon chains in the process of crystallisation. The free rotation or 'spinning' of a long hydrocarbon chain in crystals of the substituted ammonium halides provides another example of flexibility of molecular structure where rigidity might have been expected.

The absence of all but a centre of symmetry in the molecules of crystalline benzene is recorded; but observations of the diffraction of electrons in the vapour have shown that the carbon atoms form a "regular hexagon with an edge-length of 1·39 ± 0·03 A.U." Nevertheless in Fig. 16, a zigzag ('chair') configuration is assigned to the two aromatic rings of diphenyl. This also exhibits a centre of symmetry, so that the rings must be coplanar, instead of being twisted relatively to one another about the long axis of the molecule. The report concludes with an account of the results obtained by the X-ray analysis of long-chain hydrocarbons, fatty acids, synthetic polymers, natural polymers such as cellulose and rubber, and protein chains such as the silk fibre, in reference to which Meyer and Mark have already published an important volume.

The third contribution, on "Directed Valency from the Point of View of Quantum Mechanics", gives a most illuminating account of the way in which the newer quantum mechanics has replaced the localised electrons and electron orbits of earlier theories by electron clouds, the density of which is a measure of the probability of the electron being found at a particular point. The way in which the fine structure of the L-shell has been correlated with the angles between the bonds in compounds of oxygen, nitrogen and carbon is explained very clearly; and an interesting estimate is given to the effect that work amounting to 600 cal. per mol. would be required to bend through 5° the straight bonds between HC and CN in hydrogen cyanide, whilst 1000 cal. per mol. would be required to distort by 5°–10° the tetrahedral angles between the bonds in diamond.

(*c*) Prof. Mecke's report on "Band Spectra and Stereochemistry" covers only thirty pages and is therefore perhaps too concise for chemical readers who are not already familiar with the subject. In particular the equations which are used to describe the P, Q and R branches of a band spectrum might have been accompanied by a description of the phenomenon in general terms, for the benefit of the non-mathematical reader. In view of its great importance as evidence of complete symmetry in gaseous molecules, the phenomenon of alternating intensities in band spectra might also have been described in greater detail by the author who discovered it.

One of the most interesting features of this report is the description of the 'binding constant', k, which Mecke himself has introduced to represent the work which would be needed to double the distance between the atomic nuclei of a molecule, on the assumption that Hooke's law remained valid throughout. A paragraph in small print explains that, in order to double the size of a water molecule by stretching the bonds, an expenditure of about 1,000 kilogram calories per gram molecule would be required, whereas the work done against cohesion in doubling the volume of liquid water would be about 8 kilogram calories.

The values of k, as calculated from the vibration frequency and the moment of inertia of the molecule, are fairly constant at 27, 54 and 77 volts, for single, double, and triple bonds, and can thus be used to diagnose the nature of the bonds. Chemists will, however, be very reluctant to accept the conclusion that the structure of carbon dioxide is similar to that of carbon monoxide, containing quarter-polar quadruple bonds, with three covalent linkages between carbon and oxygen, thus:

$$\begin{array}{ccc} :C:::O: & :O:::C:::O: & :N::N:::O: \\ \text{or } \overset{-}{C}\equiv\overset{+}{O} & \text{or } \overset{+}{O}\equiv\overset{--}{C}\equiv\overset{+}{O} & \text{or } N\equiv\overset{-}{N}\equiv\overset{+}{O} \\ \text{Carbon monoxide.} & \text{Carbon dioxide.} & \text{Nitrous oxide.} \end{array}$$

Indeed, the evidence for this formula is not very convincing, since the 'binding constant' is only 61 volts for CO_2 and 62 volts for N_2O, as compared with 54 volts for the double bond in C_2H_4 and 70 volts for the triple bond in C_2H_2. Other values recorded in the table are 55 volts for CS_2 and SO_2, 78 volts for the triple bond in HCN, 77 volts for CO and 85 volts for N_2.

(*d*) Prof. Dadieu's report on "Raman Effect and Stereochemistry" supplements Prof. Mecke's more general spectroscopic report. Raman spectra can be produced by symmetrical vibrations, which cannot be excited by the absorption of infra-red radiation; they therefore provide a valuable method of diagnosing the origin of the individual lines. Moreover, by means of a weak Raman line, with the vibration frequency of a double bond, Dadieu and Kohlrausch have detected the presence of HNC as a minor component in prussic acid, the spectroscopic properties of which are predominantly due to HCN.

(*e*) It would be difficult to praise too highly the report by Wolf and Fuchs on "Structure in Relation to Electrical Properties". In the theoretical sections, the symbols differ from those used in Debye's book on "Polar Molecules", and are rendered obscure by the use of too many subscripts. The methods for determining dipole moments are, however, adequately described, illustrated and discussed; and it is a special merit of this report that it deals also with the cognate phenomena of depolarisation of scattered light by anisotropic molecules, and the Kerr effect of double refraction in an electrostatic field. The collection of experimental data is remarkably complete, and has the advantage of being classified in a series of more than twenty tables, so that abundant data are at once available to illustrate every theoretical point that is raised by the author, or that may occur to the reader. In particular, the problems of free and impeded rotation and of distortion of valency direction are presented with full experimental evidence for the conclusions that are reached.

(*f*) Dr. Werner Kuhn's report on "Optical Activity" deals with the fundamental property of optical rotatory power, which led to the initial development of three-dimensional chemistry by Pasteur nearly a century ago. It is therefore unfortunate that in an early paragraph the author appears to underrate the importance of the classical experiment, whereby Pasteur first resolved sodium ammonium racemate into the *d*- and *l*-tartrates, since he claims that (by making use of the selective decomposition of *d*- and *l*-azidopropionic dimethylamide by circularly polarised light) he has developed the "only method whereby up to the present the optical antipodes of a racemate can be separated arbitrarily without the aid of other optically-active substances". A similar criticism is invited by a statement that "optically active compounds containing one asymmetric carbon atom, e.g., the compound

had already been discovered in the time of van't Hoff", whereas in fact a compound of this type was first resolved by Pope, Perkin and Wallach in 1909, which was thirty-five years after the publication of van't Hoff's "Chemistry in Space", although two years before his death in 1911.

Dr. Kuhn's report consists mainly of a description of the views which he has himself put forward during the past four years; and a considerable part of the report has been taken verbatim from a recent monograph by Kuhn and Freudenberg under the title "Drehung der Polarisationsebene des Lichtes"[1]. The hypothesis is adopted that optical rotatory power is developed by an unsymmetrical coupling of electrons, such that when one vibrates in a north-and-south plane the other has a component vibration in an east-and-west plane. Thus the major component of the rotatory power of azidopropionic ester is attributed to the coupling of the electrons of the azido-group (which gives a weak absorption band in the middle ultra-violet) with the electrons associated with the asymmetric carbon atom (which is supposed to possess an extremely intense band in the inaccessible Schumann region). The development of optical activity by the coupling of electrons is described by him as "vicinal action".

In this connexion attention may be directed to a letter in NATURE of April 19, 1924, on "Induced Asymmetry of Unsaturated Radicals in Optically-active Compounds"[2], which is cited in Kortüm's recent monograph, but not in the present report. In this letter, the hypothesis was put forward "that unsaturated chromophoric groups can be made asymmetric by induction from a fixed asymmetric centre, and thus develop optical activity"; "induced asymmetry" was, however, only attributed to the chromophoric groups *when coupled sufficiently closely to an asymmetric complex*. This hypothesis was based on the experimental fact "that the dispersion equations for camphor and its derivatives are haunted by a low-frequency term *the period of which is definitely characteristic of the ketonic group*."[3] In a similar manner, Kuhn was able to show some years later that the azido-group which (like the ketonic group) normally contains a plane of symmetry, nevertheless produces an important partial rotation in the azido-propionic esters. The optical activity which was attributed in 1924 to the "induced asymmetry" of the unsaturated radical is attributed by Kuhn to the "induced anisotropy" of the absorption band of this radical; but the correct term for the phenomenon is obviously "induced dissymmetry" or "induced optical activity", since anisotropy alone cannot produce optical activity, and complete asymmetry although usual is not essential.

Dr. Kuhn's model leads to mathematical equations of a type which had already been developed by Drude in 1906; but these have been adapted to absorption bands of a form which agrees more nearly with that which is observed in practice. These equations, however, now provide a numerical estimate of the distance between the coupled electrons, with the interesting result that the distances thus calculated are considerably greater than the extreme linear dimensions of the molecule. Another important deduction states that, since the process of coupling affects both electrons, the sum of the partial rotations (for example, as expressed by the numerators in Drude's equation) must be zero. A 'simple rotatory dispersion' then results, as the algebraic sum of partial rotations of similar frequency, when *all* the active absorption bands are in the Schumann region, whilst complex and anomalous rotatory dispersions result when one or more of the bands is in the visible or in the accessible ultra-violet region.

(*g*) Part I concludes with a report by Dr. Stefan Goldschmidt on "Reaction Velocity". This report (of which only one-half is included in the third instalment) does not call for detailed criticism at this stage, since it consists mainly of a review of the evidence for and against the doctrine of "Steric Hindrance" in organic reactions of many different types. It does not therefore break new ground in the same way as the reports which precede it, but it will nevertheless be of real value to those who require a guide to the literature dealing with this phenomenon.

Nomenclature in Lepidoptera

The Macrolepidoptera of the World: a Systematic Description of the hitherto known Macrolepidoptera. Edited by Prof. Dr. Adalbert Seitz. Supplement to Vol. 1: *The Palæarctic Butterflies.* Pp. vii+399+16 plates. (Stuttgart: Alfred Kernen, 1932.) 132 gold marks.

IN the supplement lately issued to the volume of Seitz's "Macrolepidoptera" dealing with the palæarctic butterflies, the editor and his collaborators have, within their self-imposed limits, produced a work of great value and of high interest. How far these limits will commend themselves to students of the various groups concerned, may be doubtful; it is at least certain that disputable points have been carefully considered, and that in most of the decisions arrived at account has been taken of the dictates of common sense.

"It is impossible in these supplementary volumes," the editor remarks, "to take up an extreme attitude either in the nomenclature or with the giving of new names." That the latter proceeding can be carried to excess is evident from the fact that more than one hundred forms of one species of *Parnassius* have each received a name. Most people will agree with the editor that "nomenclature itself is not a science, but that it should be an aid to science. As soon as it proves itself the reverse it is worse than useless and should be opposed." There can also be little doubt that names which are merely abbreviated diagnoses, such as *croceosemivirgatus-cœrulescens*, should be disallowed as a retrograde step towards the system happily reformed by Linnæus. At the same time, the trinomial system now so widely adopted serves a useful purpose in grouping together, under a common specific designation, various closely related but distinct forms which may be judged not to be deserving of specific rank. But here also restraint is necessary; a tendency of the trinomial to become a quadrinomial or multinomial system should generally be checked.

In the matter of specific names, assent will probably be given by most lepidopterists to the principle laid down by Prof. Seitz that the form first described, even when it is a comparatively rare and inaccessible 'subspecies', should retain the specific appellation; other subspecies adding their distinctive designations to the common name denoting the species.

An inherent difficulty in the whole matter is the fact that nomenclature has to presuppose the existence of hard and fast lines where such do not exist in Nature. Perfect correspondence between the system and the facts is unattainable; every student will have his own idea of the best form of compromise. What is to be aimed at in practice is the establishment of a well-considered standard of nomenclature, sufficiently reasonable to induce students to sink their individual opinions and preferences for the sake of general agreement.

The editor and his collaborators have borne in mind throughout that their undertaking is mainly intended as a work of reference and not of criticism. This justifies the admission of many new names that from a strictly scientific point of view might well be disallowed. On the whole, they have exercised a wise discrimination, and have been guilty of few, if any, sins of omission.

Leaving aside the topics dealt with in the preface and introduction, we have found little to call for special notice. A discoidal cell (p. 8) should not be called "open" merely because it is not bounded by a black streak. The view expressed (p. 93), that a name should only be given when specimens can be denominated even without the particulars of the locality and the date, seems, on the whole, reasonable. But it would not be difficult to suppose cases where the rigid application of such a rule might be inadvisable.

The English version of the book is for the most part well executed; but one is inclined to suspect that the intricacies of the English language have occasionally been a little too much for the translator. The plates, sixteen in number, reach a high standard of merit.

Short Reviews

Business Rationalisation, its Dangers and Advantages considered from the Psychological and Social Standpoints: Three Lectures given at the London School of Economics under the Heath Clark Bequest to the National Institute of Industrial Psychology. By Dr. Charles S. Myers. Pp. vii + 76. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 3*s*. 6*d*. net.

THIS book attempts to give a more comprehensive picture of rationalisation than is suggested by its title, and in emphasising the importance of the human factor in rationalisation and the bearing of rationalisation on the general structure of society the book makes a needed and valuable contribution. In discussing the significance of rationalisation, Dr. Myers has scarcely placed sufficient emphasis on the growing tendency under modern conditions for the really progressive large combines to display in their general policy a remarkable approximation to the spirit of service characteristic of what might be termed national service or public utility departments. This tendency is likely to become even more pronounced, and public opinion will judge rationalisation largely by the extent to which service rendered to the community in the broadest sense dominates the policy of the rationalised combines.

On the question of leadership and particularly on the development of leadership by scientific management in industry Dr. Myers has little to say, though he notes the importance of personality, and his treatment of the dangers of rationalisation is too academic. Similarly in discussing its advantages, Dr. Myers has rather strangely omitted to set rationalisation in its true perspective in an age which demands increasing world co-operation, or to discuss the significance of international industrial co-operation for world peace. More care might have been taken to distinguish rationalisation from mere amalgamation, for such confusion is responsible for widespread misunderstanding of, and opposition to, valuable and overdue schemes of rationalisation in certain industries.

The subject headings of the chapters are by no means happily chosen; some of the most important observations on the dangers of rationalisation are to be found, for example, in the other chapters. The book just misses an opportunity for a timely exposition of rationalisation from an aspect which is of growing importance but often overlooked.

R. B.

Industrial Psychology in Practice. By Henry J. Welch and Dr. George H. Miles. Pp. xiii + 249. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 7*s*. 6*d*. net.

NUMEROUS examples drawn from many different industries, illustrating the practical results which have already attended the application of the methods and principles of industrial psychology to commercial and industrial problems, are recorded in this volume, which demonstrates convincingly the value of such applications alike from the point of view of the worker and of the employer. The fact that investigations of working conditions such as lighting, heating and ventilation, noise, or hours of work, fatigue and monotony and the most effective method of carrying out a specific operation or process have almost invariably increased the efficiency or output of the worker has frequently led to an even more important result being overlooked—the improvement in the health of the worker, who is also less fatigued by the effort required for the greater output under the new conditions. Industrial psychology is clearly of the utmost importance from both points of view and this book tends to redress the balance of emphasis by stressing the importance of such methods to the worker in the prevention of accidents, in the planning of work and elimination of waste, the selection and training of personnel, etc.

Material has been taken freely from the reports of the Industrial Health Research Board, the Home Office Safety Pamphlets, the investigations of the National Institute of Industrial Psychology, as well as from foreign sources, and the book demonstrates conclusively the immense value of the human sciences to the community, and the wide possibilities in the settlement of human problems not by opinion, rule of thumb or tradition, but by scientific methods based on ascertained facts. It should be of great service in enlisting further support for the work of the Industrial Health Research Board and the National Institute of Industrial Psychology, and in encouraging the wider application of such methods in industry.

Bibliographical Survey of Vitamins, 1650–1930: with a Section on Patents. By Mark H. Wodlinger. Compiled by Ella M. Salmonsen. Pp. viii + 334. (Chicago: Mark H. Wodlinger, 1932.)

THE literature of the vitamins now runs to several thousand original papers. In this bibliography, more than 11,000 publications are mentioned; 326 references appear in the historical section covering the period 1650–1910. Thereafter the papers of each year are listed separately, and from 1916 onwards a separate section is devoted to each vitamin: vitamin E first appears in 1921.

The earlier references are, of course, to the deficiency diseases, which we now know to be caused by the absence of a particular vitamin from the diet, and also to medicaments such as cod liver oil which owe their efficacy to their content of vitamins, although this was not realised at the time their use was originally advocated. These early references will be of special value to those interested in the historical side of the subject and might form the basis of a study of the development of our knowledge of the real cause of different deficiency diseases.

The references to each vitamin are arranged in the alphabetical order of the authors' names: provided the name is known it takes but a moment to find any particular paper, even although the year of publication is not known. It would take only a short time to extract from these pages a list of papers dealing with any particular aspect of the vitamin problem, since the title of each paper (or book) is given in full.

This book should be of great use to all workers in this field: it supplements the reviews and monographs on the vitamins and precedes the issue of *Nutrition Abstracts and Reviews*, which should now provide an adequate index to the literature. In the last section the list of 240 patents should be of value to manufacturers or to research workers who may wish to patent their process.

A History of the Birds of Suffolk. By Claud B. Ticehurst. Pp. xi + 502 + 18 plates. (London and Edinburgh: Gurney and Jackson, 1932.) 24*s.* net.

WITH the progress of ornithological interest it is impossible to work with a book that is forty-five years old, however good it was when published. Those interested in the birds of Suffolk will welcome an up-to-date work by one who is singularly competent to write it. From the hours of a busy life, Dr. Claud Ticehurst was able to take some leisure and to make his notes and record his observations. He has spent twenty years in producing this volume, seventeen of which were spent in Lowestoft.

In the introduction are given a description of the country; changes in the avifauna; migration; a list of the collection of Suffolk birds; the names of former Suffolk ornithologists and the scope of the volume explained. The order and nomenclature used are those of the "List of British Birds" published in 1915. We think the 1923 "List" would have been preferable. The species are treated on modern lines, doubtful records examined and the latest and most reliable views expressed. The photographic plates add to the work and the map of Suffolk is, of course, a necessity.

Einführung in die Mechanik und Akustik. Von Prof. R. W. Pohl. (Einführung in die Physik, Band 1.) Zweite verbesserte Auflage. Pp. viii + 251. (Berlin: Julius Springer, 1931.) 15.80 gold marks.

THIS second edition of Prof. Pohl's elementary treatise should need little commendation to the notice of English readers. Its treatment of the subject is well off the lines of the traditional method and, both in its insistence on apt experimental illustration, and in the small demand it makes on the reader's mathematical knowledge, it forms an effective foil to the conventional English textbook. It is to be hoped that a translation, modified a little (in scope rather than in outlook) to suit the work of the junior university and senior classes of schools, will make the book available to those who cannot read the German text. Despite the excellence of the text, such modifications would seem to be needed, more especially in that section which deals with acoustics.

A notable feature of the book is its wealth of illustrations, many of them produced most effectively as deep black silhouettes.

A. F.

Early History of the Determination of Atomic Charge

ATOMICITY is a characteristic of twentieth century physics, so that modern physics may be said to begin with those early investigations by which the atomic nature of electricity was first established. The facts relating to early investigations of the atomic charge are scattered through the literature of the subject, and it will be of interest to bring them together in a brief account of the development of the methods which led to the accurate determination of this fundamental constant.

That electricity has an atomic structure appears first to have been suggested to explain Faraday's laws of electrolysis, on the supposition that the charge on a monovalent ion was the smallest separate quantity. This hypothesis was strongly advocated by Stoney and Helmholtz. It follows from Faraday's experiments that if E be the charge on a monovalent ion in a liquid, and n the number of molecules in a cubic centimetre of a gas at 15° C. and 76 cm. pressure, the product $n.E$ is $1 \cdot 24 \times 10^{10}$, E being expressed in electrostatic units. This E is taken as the *fundamental atomic charge*.

The quantities n and E could not be deduced separately from experiments on electrolysis, and in the earliest attempts to determine E the above value of $n.E$ was used with approximate estimates of n. All that was known about n prior to a direct measurement of an atomic charge, was that "it lies between the limits 10^{18} and 10^{21}" as stated by Sir J. J. Thomson in his book "The Discharge of Electricity through Gases" published in 1898, where he also gives a description of the first experiments on the direct determination of the atomic charge made by Townsend,[1] who was at that time demonstrator in the Cavendish Laboratory, Cambridge.

These experiments of Townsend are notable as being the prototype of the investigations which led finally to the accurate determination of the atomic charge made by Millikan.

It was known that in many cases electrically charged clouds were formed when newly prepared gases were bubbled through water. Townsend conceived the idea of measuring the charge on a drop in such a cloud, which he supposed to be an atomic charge, and for this purpose he used gases prepared by electrolysis, adopting the following procedure. The total weight W of the drops in a cubic centimetre of the cloud, and the total charge Q carried by them, were found by direct measurements, but in order to determine the average charge on a drop it was necessary to find the number of drops in a cubic centimetre of the cloud; to obtain this number the weight w of a drop was required.

The weight of a drop and also its radius were obtained from the rate of fall of a cloud in a beaker, by an ingenious application of Stokes's formula for the velocity of a sphere moving slowly in a viscous medium under the action of a constant force. The first value found for an atomic charge was 3×10^{-10} E.S.U., but after allowing for the fact that the cloud contained drops with charges of different sign, Townsend[2] gave a corrected value 5×10^{-10}.

The importance of this investigation was immediately recognised, and in 1898 Sir J. J. Thomson used the same method modified in details to investigate the charge carried by ions produced by X-rays. In Thomson's experiments a cloud was formed in a closed vessel as in C. T. R. Wilson's experiments in which an ionised gas is cooled by a sudden expansion causing water vapour to condense on the ions. With this modification, it was necessary to determine the charge Q per cubic centimetre and the weight W indirectly, consequently Q was obtained from the electrical conductivity of the gas and W by estimating the amount of moisture condensed on ions by the expansion.[3] The gases were ionised by X-rays and the values $6 \cdot 5 \times 10^{-10}$ E.S.U. and $6 \cdot 7 \times 10^{-10}$ E.S.U. found for the charge on a drop in air and hydrogen respectively. Later he obtained the value $6 \cdot 8 \times 10^{-10}$ for negative ions generated by the action of ultra-violet light.[4] In a subsequent determination[5] which he considered to be more accurate, he used a radioactive substance to ionise the gas, obtaining for the value of the atomic charge $3 \cdot 4 \times 10^{-10}$.

The determinations of Townsend and Thomson involve various inaccuracies, and also the serious uncertainty in the assumption that each drop in the cloud carried a single atomic charge. Millikan states that, in the clouds produced in ionised gases by expansion, some of the drops may carry one, some two, some ten or almost any number of unit charges, though this does not imply that before condensation the ions in the gas have multiple charges.

There remained, in addition, the difficulty of establishing a relation between the charge e on an ion in a gas and the charge E on a monovalent ion in an electrolyte. A method of showing that these charges are identical was first given by Townsend[6], who showed that if e be the charge on an ion in a gas, U its mean velocity in the direction of an electric force Z, and K the coefficient of diffusion of the ions, then the value of $n.e$ is obtained from the equation $U/K = n.e.Z/P$ where P is the pressure of a gas containing n molecules per cubic centimetre at the temperature at which U and K are determined ($P = 10^6$ C.G.S. units).

In order to find the product $n.e$, Townsend devised a method by which he measured the coefficient K, and taking the mean values of K for moist and dry gases with the corresponding values of U obtained by Rutherford, he found the following values for $n.e \times 10^{-10}$: air $1 \cdot 35$; oxygen $1 \cdot 25$; carbon dioxide $1 \cdot 30$; hydrogen $1 \cdot 00$.

These values of $n.e$ were so near the value $1 \cdot 24 \times 10^{10}$ of $n.E$ for monovalent ions in a liquid that Townsend was able definitely to state that the charge on ions produced by X-rays and the charge E on a monovalent ion in a liquid are the same. In later investigations in which the ions were produced in various ways, he found that the value of $n.e$ for negative ions in gases was in close agreement with the value of $n.E$ for electrolytic ions.

Further progress in the accurate determination of e was made when H. A. Wilson introduced an important improvement into the method of finding the charge on a drop, whereby it was possible to avoid the uncertainty of dealing with drops with an unknown number of atomic charges. The cloud was formed in the ionised gas by expansion, in an apparatus containing two horizontal parallel electrodes, so that it was possible to establish a vertical field Z in the space where the cloud was formed. A retarding or an accelerating force, $Z.e$, was thus superimposed on the force of gravity w acting on each drop. The weight w of a drop was determined by measuring the velocity when Z was zero and by applying Stokes's formula as in the original method. The charge e was determined by finding the change in the velocity when the force $Z.e$ and w acted together. In this method it was unnecessary to find the number of drops in the cloud. It was observed that the change in the velocity due to the electric force was not the same for each drop, since the cloud appeared to fall in groups of drops with charges in the proportion 1 : 2 : 3.

This important observation showed that the charge on a drop, if not equal to, was a multiple of the smallest charge. H. A. Wilson gave $3\cdot1\times10^{-10}$ as the value of the atomic charge according to this method.[7]

It is well known that the most accurate determinations of the atomic charge were made by Millikan in the period 1909–1916.[8] As it was unnecessary to find the number of drops in the cloud in order to determine e, Millikan applied H. A. Wilson's method to single drops. Inaccuracies due to evaporation were avoided by using drops of non-volatile oil, which were placed in electric fields of such strength that they could be made to move against gravity or held in suspension at will. A single drop could thus be kept under observation for long periods. He tested Stokes's formula, which had been assumed by his predecessors, obtaining an empirical correction to it in the case of small drops, and his very consistent results[8] showed that the charges carried by drops were always exact multiples of the atomic charge $4\cdot77\times10^{-10}$ E.S.U.

The earliest investigations of the atomic charge had an important bearing on the interpretation of the experiments made to determine the ratio of the charge e to the mass m of an electron. The first trustworthy determinations of the ratio e/m were made in 1897 by Wiechert,[9] Kaufmann,[10] and Thomson,[11] who found that the ratio e/m for cathode rays was about 1/2000 of the ratio E/M of the atomic charge E to the mass M of an atom of hydrogen. It was known from experiments on electrolysis that the ratio E/M was $2\cdot9\times10^{14}$ while the best experiments gave $5\cdot3\times10^{17}$ for the ratio e/m, and from the first it was suggested by Wiechert that the charges E and e were equal and consequently that the mass m was about $M/2000$. This suggestion, however, could only be regarded as a plausible hypothesis until the identity of the charges E and e had been established in 1899, in relation to which Townsend's investigation of the product $n.e$ ranks in importance with the accurate determination of the atomic charge e.

Scientific and Industrial Research*

THE seventeenth annual report of the Department of Scientific and Industrial Research covering the period August 1, 1931–July 31, 1932, appears appropriately as if to punctuate the tributes to the importance of research in our national life which have recently been paid by high authorities in finance. A more impressive picture of the manifold ways in which scientific research is daily applied not merely to the solution of our industrial problems but also to the service of the innumerable needs of a civilised community than is contained in the annual reports of this Department it is difficult to imagine. The present report, including the brief report of the Privy Council, signed by the Right Hon. Stanley Baldwin, and the longer report of the Advisory Council, over Lord Rutherford's signature, is no exception to the rule. Lucid as are these reports and the summaries of the work carried out by the National Physical Laboratory, the Chemical Research Laboratory, the research associations, and under the direction of some forty-five research boards and committees, a popular exposition of the matter contained in them should be invaluable propaganda and assist the ordinary citizen to appreciate the magnitude of the contribution thus made to the necessities and luxuries of his daily life—food and clothing, air and water supply, transport and housing, business and pleasure. Appendices to the report deal with finance, publications and the personnel of the various boards and committees.

There is no department of State in which the beneficial influence of the Department of Scientific and Industrial Research is not felt and no proportion of the national income is more profitably spent than that controlled by this Department. *It is satisfactory to find that the expenditure* detailed in the current report shows only a slight reduction on that recorded in the previous report; the gross expenditure for the year amounted to £695,677 as compared with £740,520 in 1930–31, and the actual expenditure to £534,700 as against £555,691. Receipts showed a decrease from £184,829 to £160,977, most of which is represented by decreased receipts of the National Physical Laboratory from outside bodies and firms, Government departments, etc. The net expenditure on headquarters administration is £24,900, grants for research amounted to £34,398 net, and to research associations £82,307, an increase of £6,652 on the previous year. Expenditure on the Geological Survey and Museum amounted to £62,730, and on the National Physical Laboratory to £200,754 gross, against which receipts amounted to only £93,982 instead of £104,706 in 1930–31. The net cost of the Chemical Research Laboratory was £19,450, of radio research £10,482, of water pollution research £10,796, fuel research £82,707, receipts diminishing the gross expenditure on the latter by £6,033. The major part of the expenditure on food research is met by a grant of £30,502 from the Empire Marketing Board and this and other receipts bring the gross expenditure of £46,997 to £11,530 net. Similarly, receipts amounting to £7,680 and £7,896 reduce the expenditure on building and forest products research to £34,519 and £33,792 respectively.

---

* Department of Scientific and Industrial Research. Report for the Year 1931–32. (Cmd. 4254.) Pp. iv+193. (London: H.M. Stationery Office, 1933.) 3*s*. net.

Nineteen research associations received grants during the year, and the report records that certain of these associations have been able to record a marked increase of industrial support during the past year while others are hopeful of attaining similar success in the near future. The British Electrical and Allied Industries Research Association now derives approximately one-half of its industrial income from supply undertakings, and the majority of lead manufacturers in the country are now members of the British Non-Ferrous Metals Research Association. Refractory material makers are supporting more strongly the British Refractories Research Association, and the voluntary levy scheme launched by the Wool Industries Research Association two years ago is now working smoothly but, mainly owing to bad trade conditions, has not yet shown signs of yielding an income sufficient to meet the Association's present scale of expenditure.

On the other hand, the British Cast Iron Research Association, in spite of the highly important and eminently practical research results to its credit, is experiencing great difficulties in maintaining its industrial income, while membership of the Cutlery Research Association has declined from fifty to ten firms in two years. In view of this lamentable lack of interest in the Association's investigations, the Department concluded that continued expenditure of the public funds at the disposal of the Association was unlikely to lead to results of benefit to the industry as a whole and, with the consequent surrender of these funds, *termination of the Association's activities* has been inevitably involved.

Reviewing the work of the research associations as a whole, the report emphasises the importance of their work to industries other than those designated by their respective titles and notes movements for widening the basis of industrial support. Few of the research associations appear to be in favour of a compulsory levy scheme, and accordingly the Advisory Council is unprepared at the present time to make representations in favour of introducing a general measure to authorise the compulsory adoption of a levy.

The general interest of the work of the research associations may be illustrated by a few typical examples selected from many to which space forbids even reference. In the iron and steel industry, research has reduced the consumption of coal per ton of finished steel from 31 cwt. in 1924 to 23 cwt. in 1930, representing an estimated average saving on coal used after the pig iron stage of more than £1,468,000 on the 1930 production. Important work on smoke abatement, refractories, etc., is being carried out in collaboration with other interests concerned. With the support of the water-supply authorities and others, the Non-Ferrous Metals Research Association has commenced a study of the bursting of water-pipes by frost by a thorough investigation of the properties at low temperatures of the materials used for them. The Association is also investigating the quality of galvanised iron with special reference to the corrosion of hot-water tanks and the retention of brightness of polished white metals, such as are used for shop fronts, name plates, etc. These are matters in which the ordinary citizen or householder is as interested as the industrialist, and the same may be said of investigations carried out by the Electrical and Allied Industries Research Association on conducting leads in gas-filled lamps used for office and factory lighting, which have enabled a considerable reduction in the rise of temperature in the fittings to be effected and simultaneously reduced the fire risk. The same Association has developed a simple portable apparatus for determining the conductivity of the ground along a proposed cable route, so that the correct size of cable required to carry the current can be ascertained. Other investigations have been concerned with the efficiency of electrical earthing and on the cause and prevention of interfering noises on telephone lines.

The Refractories Research Association provides a striking example of an association of which the work is of general interest, and closely associated with its investigations are representatives of the Institution of Gas Engineers, the National Federation of Iron and Steel Manufacturers and the British Pottery Manufacturers' Federation. These investigations have ranged over such subjects as the durability of refractory materials and its improvement, the permeability of refractory materials to high temperatures and changes in physical structure during the firing of fire clay goods.

The Research Association of the British Paint, Colour and Varnish Manufacturers has continued its investigations on the measurement of the physical and mechanical properties of paint, varnish, and lacquer films, the hiding power of paint, the relations between crystal structure, surface characteristics and pigmentary value. The recently formed Research and Standardisation Committee of the Institution of Automobile Engineers, to which the Department contributes financially, has occupied itself with problems of cylinder and piston wear, lubrication, and with such problems of general interest as silencing, for which a new instrument has been designed.

The Cotton Industry Research Association is not only carrying out important fundamental studies of dyestuff solutions, the dyeing process, and mercerisation, but has also made special efforts to demonstrate to its members the practical value of its operations. More than two thousand visits were paid to mills and works during the year by its liaison staff, and the prestige of the Association is distinctly greater in the trade than a year ago.

The Wool Industries Research Association has been concerned with the various causes of fading such as light and atmosphere, laundering and perspiration, which are often of immediate interest to the public. The Linen Industry Research Association has similarly been concerned with wearing properties under laundering as well as with levelness and regularity of weave. The Launderers' Research Association has been concerned with detergents as well as with the mechanical conditions, with the object of decreasing attrition and the prevention of felting of wool, etc.

Among the problems occupying the attention of the Leather Manufacturers' Research Association have been the deterioration of leather on storage, the factors responsible for dermatitis associated with dyed leather, while the Boot, Shoe and Allied Trades Research Association has designed new lasts on which the contracts for the Army marching boots are being carried out, using vegetable tanned leather curried according to the Association's recommendations. The sound-absorption of rubber flooring in auditoriums, improving the resistance of rubber to oils, ageing, and water absorption are directions in which the Rubber Manufacturers' Research Association is assisting the utilisation of rubber and the revival of this depressed industry.

The Research Association of British Flour Millers is investigating the blending of wheat to give flour of regular and improved qualities. The Research Association for the Cocoa, Chocolate, Sugar, Confectionery and Jam Trades has been concerned with such varied problems as the 'solubility' of cocoa, standardised specifications of, purity of materials, including wrappers, coatings of sugar crystal, while the Food Manufacturers' Research Association has carried out successful investigations on the canning of kidneys and liver as well as on the development of satisfactory gums and pastes for labels.

These investigations are, however, only a fraction of those concerned with food with which the Department as a whole has been concerned. The importance of food in the maintenance of health and in the control of disease is being more and more widely recognised in days when emphasis is laid on preventive as against curative methods. It would be difficult to overstress the importance to public health of some of the work which is being carried out to preserve the freshness of food. Merely to enumerate the investigations on the storage of chilled beef, opening up the prospect of chilled beef from Australia being marketed in Great Britain, on the storage of bacon and ham, on canning problems, on the smoke-curing of fish, on the preparation of fish livers for treating pernicious anæmia and on the storage of fruit and vegetables. should bring home to the most unimaginative citizen the value he receives from the expenditure of this insignificant proportion of the national reserve, even if its importance to home industries and to the shipping companies is less apparent.

The importance of the physical and chemical survey of the coal resources of Great Britain has been enhanced by the events of the last two years, and other work carried out under the Fuel Research Board dealing with the scientific utilisation of fuel, including low temperature carbonisation, represents an attack on perhaps the most crucial problem with which the Department is concerned, bearing directly on the unemployment problem as well as, through its reaction on atmospheric pollution, on public health.

Again, it is a simple matter for the ordinary citizen to appreciate the immense importance of the work of the Building Research Board outlined in this report, whether as applied to the testing of building materials, the weathering of materials, or the design of reinforced concrete piles for the foundations of big buildings, momentary stresses in which are now being measured by an ingenious application of radio methods. He will readily grasp also the significance of the researches on steel structures now so widely used in building, and the activities of the Radio Research Board, which are frequently as closely related to the needs of the ordinary listener and amateur as to those of the Post Office, the Admiralty, the War Office, the Air Ministry and other bodies at the request of which many of them were originated. The work of the Forest Products Research Board bears directly on the life of timber and the efficiency with which it can be preserved against insect or fungoid attack, whether by the death watch beetle for example or by dry rot, and once again touches many a householder closely.

To do justice to the activities of the National Physical Laboratory might well require volumes, and only a few examples can be given. In the William Froude Laboratory, research on wind resistance has indicated ways in which the air resistance of most types of vessel can be reduced by about 30 per cent, while other improvements have been effected in the design of small coaster vessels as well as in the humble barge, the improved design showing on towing tests a 33 per cent improvement in speed for slightly less power. The National Physical Laboratory played an important part in designing the high speed seaplanes which won for Great Britain the 1931 race for the Schneider trophy, as well as in the development of new and safer types of aircraft. Other work assists in the provision of improved materials for industry, including steel and steel alloys capable of withstanding the high temperatures at which modern machinery such as turbines and aircraft engines must work, and workers in other sections of the Laboratory again are investigating the glare effect of different systems of street lighting, the best beams for traffic control signals, the transmission factors of coloured railway signal lights and the lighting of docks, quays and their approaches. It needs little imagination to realise what advance in these fields means not merely to industrial efficiency but even more in the elimination of much suffering and loss of life.

The field covered by the work of the Chemical Research Laboratory is almost equally wide, ranging from products for treatment of sleeping sickness in human beings and in animals, to the preparation of synthetic resins, corrosion research, researches at high pressures, tar research and water pollution. With the latter subject a special board is concerned, and following on the survey of the River Tees recently carried out, one on the River Mersey is now projected.

Space does not permit further reference to many activities of the Department which are of scientific as well as of industrial and general interest. This brief review contains no account of important metallurgical researches for which the Department is responsible, or of its investigations on electrodeposition, lubrication or dental problems. Mention should, however, be made of the Geophysical Survey Research Committee, which has now completed its work and through the activities of which the danger that the development and use of this new applied science in Great Britain would be neglected has been dispelled. Sufficient has been said, however, to demonstrate the unique and invaluable contribution which the Department is making not merely to industrial efficiency but also to industrial development and the public welfare, and to indicate how essential it is in days when economy is the watchword that there should be no restriction of services which have been so productive.

Obituary

LIEUT.-COL. ALFRED W. ALCOCK, C.I.E., F.R.S.

WITH the death on March 24 of Alfred Alcock, there has passed away a type of doctor who in the past has so often graced the ranks of the Indian Medical Service—that of the surgeon-naturalist. Zoological science in India has been always enriched by the labours of distinguished medical men, of whom the late Sir Joseph Fayrer and Alfred Alcock may be taken as representing the acme of a period which will never be seen again.

Alfred Alcock was born in Bombay on June 23, 1859. His father, who was a sea captain in the days of windjammers, retired and lived at Blackheath, and there the subject of this memoir went to school and afterwards became a Westminster scholar. In the 'seventies, owing to ruinous losses due to the sudden depreciation of Egyptian Government bonds, he was taken away from school, in 1876, quite unexpectedly. He was then packed off in September of that year to Wynaad in the Malabar District of Southern India, to a coffee plantation, where he had an uncle engaged in this industry. He lived in the jungles of Wynaad and in the neighbouring native State of Cochin, and was able to observe all the operations connected with coffee-planting and also to study the birds and beasts.

As coffee planting was then obviously in the decline, Alcock obtained in September 1877 a post in a newly established firm of commission-agents in Calcutta, and on the voyage from Madras to Calcutta, the ship that carried him, the *Duke of Buccleuch*, was rammed and almost sunk by a steamer, appropriately named the *Vixen*. The commission-agent business not proving a success, he next started as a freight-broker on his own account, but soon gave that up to proceed to Chota Nagpur as an assistant to a coolie-recruiting agent, where he remained until February 1880. It is necessary to mention this, as in some ways it proved the turning point of his career, for he met there a young Bengal civilian who lent him Michael Foster's "Primer of Physiology", which cost the sum of one shilling, and this little book proved to him to be what the light of heaven was to St. Paul. It set his face towards natural science, and throughout the rest of his life he thought of Michael Foster (whom he had never met) with the gratitude of a disciple. He next met the Deputy Sanitary Commissioner of Chota Nagpur, Lieut.-Col. J. J. Wood, and this good man took the young Alcock to his heart and hastened him on his way with an old microscope, several timely books and many long talks on botany, natural history and chemistry. This led him to do a little body-snatching on his own in places where the poorer natives disposed of their dead, and from that source he obtained bones to study and began to read Darwin's "Descent of Man" and "Origin of Species". He had now fully resolved to become a medical man.

Alcock next became assistant schoolmaster at a large school for European boys in Darjeeling.

He was justified in applying for this appointment since during the whole of his jungle life he had assiduously read his Horace and his Homer along with the "Canterbury Tales" and the "Golden Treasury". Fate was kind to him, because his "sanitary friend", Col. Wood, immediately rejoined him in the Darjeeling district, and actually entrusted him with the tuition of his eldest boy. Quite unexpectedly, he was helped financially by his sister, who had married a distinguished officer in the Indian Civil Service, and was able to proceed to Aberdeen, to begin work in the Marischal College of that University. In 1882 he had taken first place in the class, and the medal for natural history, and was appointed University assistant in zoology. In 1883 he obtained a bursary in natural science, and in April 1885 he graduated M.B. and C.M. with honourable distinction, while later on in that year he passed eighth into the Indian Medical Service, and in October of the same year, he joined the class at Netley Hospital, where he came under the influence of the celebrated Timothy Lewis, the professor of pathology.

Alcock's interest in the beginnings of tropical medicine had already been stimulated by the lectures of Sir Alexander Ogston, the professor of surgery in the University of Aberdeen. Ogston had discerned the great significance of the discoveries made by Patrick Manson in China on insect-borne disease, and this had impressed itself so much on his mind that it remained a guiding factor for the rest of his life.

In March 1886 Alcock again sailed for India, and was first stationed at Allahabad, and on June 6 of that year he was ordered to join the 1st Sikh Infantry at Dera Ismail Khan on the Punjab frontier. There he found himself soon shot out into the Punjab desert, and had many interesting adventures, during one of which he crossed the desert of 150 miles in the middle of the hot weather, and on another occasion he had the misfortune to break his leg and lay for some time with only a native hospital assistant to look after him. In this desert he observed many cases of snake bite, some fatal, by the horned viper. His promotion was very rapid, and in May 1888 he was gazetted to permanent medical charge of the 2nd Punjab Infantry.

Regimental life had been an extremely happy experience to Alcock, but a regimental hospital did not quite satisfy his ambitions for scientific work, and soon an unexpected opportunity presented itself when he was appointed surgeon-naturalist to the R.I.M.S. *Investigator* for the zoological section of the Indian Marine Survey of 1888-92. He joined his ship at Port Blair in the Andaman Islands on November 20, 1888. These four years he regarded always as the happiest of his life, and his experiences were summarised in that fascinating book "A Naturalist in Indian Seas" published in 1902, and it was this book that obtained the highest commendation from Sir Joseph Hooker. During this time he roamed the coastal inlets and Indian Seas, dredging for Crustacea and describing the marine fauna, including many denizens of the deep hitherto unknown to science. During his travels he visited the Andaman Islands, the Cocos Keeling, Minicoy and other sparsely inhabited islands of the Indian Ocean, studying their human inhabitants and the island fauna.

In April 1893 Alcock began his association with the Indian Museum as professor of zoology in the Medical College of Bengal, and he served many happy years in this capacity until 1907. His period of service was broken in 1895 when he was appointed as surgeon-naturalist to the Pamir Boundary Commission, and spent one year at these alarming altitudes over 14,000 ft. He actually reached the tomb of Bazai at the eastern end of the Little Pamir. His report on the natural history results of the Pamir Boundary Commission was published in Calcutta in 1898, and received general recognition.

In 1896, after ten and a half years continuous service in India, Alcock returned to England on leave, and in July 1897 he married Margaret Forbes Cornwall of Aberdeen, whom he had known in his student days. In 1901 he was elected to the fellowship of the Royal Society and in 1903 was created a C.I.E.

There is no doubt that the finest work that Alcock performed in India was that of the organisation and rearrangement of the Indian Museum, which he made a model of its kind. It was here that he came under the notice of Lord Curzon, with whom he had some difference of opinion regarding the future of this Museum. He then made, too, a lasting and life friendship with Sir Leonard Rogers, and with him became greatly interested in the classification of the *Thanatophidia*, and collaborated with him on the toxicology of snake venoms. In the meantime, he had become the outstanding authority on the Crustacea of India, a group to which he had always paid special attention, and wrote the "Catalogue of the Indian Decapod Crustacea", a work for which he was awarded the Barclay medal of the Asiatic Society of Bengal in 1907. At this time he wrote numerous papers on the river crabs (Potamon dæ) and was elected natural history secretary in 1888, general secretary in 1895, and vice-president in 1901 of the Asiatic Society. In 1906 he was on furlough in England, working through the major's course for promotion at the Royal Army Medical Laboratories and at the West London Post Graduate School, and also the Lister Institute. Here he made the acquaintance of Sir William Leishman, Sir Jonathan Hutchinson and Sir Charles Martin.

In 1907 Alcock retired from the Indian Medical Service, and immediately placed himself at the services of Sir Patrick Manson and of his new School of Tropical Medicine in London. Here he felt like a new man after what he considered to be his sad failure at the Indian Museum. Manson was the magnet which drew him, and the foundation of medical zoology on a proper basis, was his aim. He became Manson's most faithful lieutenant and admirer; to him it was a pious task to defend Manson's reputation and to aid in preserving his memory, for, apart from all his discoveries and his greatness, he considered that Manson was the embodiment of the Hippocratic tradition. Henceforward he became the first teacher of medical entomology in the School of Tropical Medicine, and he added greatly to his reputation by the publication of his text-book, "Entomology for Medical Officers", 1912, which reached its second edition in 1920. This work was written in response to requests from students in his own School, and whilst directing its attention principally to the arthropods concerned in the dissemination of disease, it almost became an outline of zoology.

To thousands of post-graduate students of all nationalities, in his charming and unpretentious way, Alcock became guide, philosopher, and friend. Soon he became responsible for the foundation and establishment of the entomological collections of the School, and for the collection of poisonous snakes and other reptiles; in fact, the whole zoological fauna that make up the science of tropical medicine. He organised the Tropical Diseases Library of the School, and from 1912 onwards actively participated with Dr. A. G. Bagshawe in reviewing for the *Tropical Diseases Bulletin*, becoming the assistant director of the Bureau in 1921. He was very gratified in being elected in 1920 to the professorship of medical zoology in the University of London. His reviews of medical zoology, as indeed every letter and article he wrote, were characterised by a charming scholastic style, embroidered with a wealth of literary and classical allusions, which could scarcely be surpassed, and gave his work an air of great distinction.

Then came the War, and in his endeavours to serve his country, Alcock found himself appointed as surgeon to an Indian hospital at Brighton, but he found himself 'at sea' when armed with a scalpel, and instead devoted himself to instructing R.A.M.C. officers, proceeding overseas, in the elements of tropical medicine. The War being over, he returned to his active teaching, and in the following years he collaborated with Dr. P. Manson-Bahr in "The Life and Work of Sir Patrick Manson", which was published in 1927. He was thus afforded an opportunity of making clear the everlasting truth of medical biology as evidenced by the life story of Manson.

Alcock retired from active teaching in 1924, and had been living in seclusion at Belvedere in Kent, but in no wise did his zeal for his favourite subject abate.

It is scarcely necessary to enlarge further on his character—that of the true naturalist, and man of science, and a lover of his fellow creatures—in fact, a friend of all mankind. It was a common experience for a stranger on seeking his road in far away Belvedere to Alcock's house, to inquire the way of some whistling schoolboy, and to receive as an astonished reply, "Oh, that's where Col. Alcock lives; he is a great pal of mine." It is appropriate to quote his favourite lines:

> "Nature is made better by no mean,
> But nature makes that mean; so, over that art
> Which you say adds to nature, is an art,
> That nature makes—The art itself is nature."

His philosophy of life, like that of old Pittacus, of Mitylene, was: "The greatest blessing a man can enjoy is the power of doing good." So, when he is gone, we realise that the era of the pioneers of tropical medicine is closed.

Alcock was an LL.D. of the University of Aberdeen, and a corresponding member of the Zoological Societies of London and of the Netherlands, and also of the California Academy of Sciences.

DR. JOHN BELLING

DR. JOHN BELLING, elder son of the late John Belling, inspector of Army Schools, who died on February 28 in San Francisco, was born at Aldershot, England, on October 7, 1866. He taught in various schools, attending lectures meanwhile at London and Birmingham, and obtained a London B.Sc. (Hons.). In later life he was given the honorary degree of Doctor of Science by the University of Maine in 1922. He lectured in the Horticultural College at Swanley, England; and later at Llanidloes, Wales, in 1900–1. Shortly after this he went to the British West Indies where he became investigator in the Department of Agriculture. In 1907 he went to the Florida Experiment Station as assistant botanist and carried out important researches there on hybrid beans.

Shortly after the War, Belling went to the Carnegie Institution of Washington as cytologist in the Department of Genetics, and was associated with Dr. A. F. Blakeslee in the investigation of the chromosomes of *Datura*. Here his genius in microscopy and his philosophical insight opened up a new field in the study of the behaviour of chromosomes and in the interchange of segments between non-homologous chromosomes. Belling was subject to periods of depression during which he did some of his most brilliant work. Believing that it was important for him to have a change of scene, he was transferred by the Institution to Berkeley, California, where he worked in a corner of Prof. E. B. Babcock's laboratory, continuing his fundamental researches on the structure of chromosomes in hyacinths and various lilies. In these investigations, under superlative technique, he believed he was able to see structures, which on account of their number and size, he identified with genes.

Belling was the author of a book on the use of the microscope, which has been eminently successful. He had also made considerable progress with a work on the study of the chromosomes.

After the Sixth International Congress of Genetics, held in Ithaca last summer, a number of foreign delegates travelled to Berkeley to examine Belling's preparations showing the structure of the chromosomes, and to discuss with him his interpretations of them. He was also the author of a small book of verse, "The Life-World. Poems of Science" (published by the Margaret Mary Morgan Co., 619, California Street, San Francisco). It contains sixty poems concerning scientific (chiefly genetic) phenomena and also three others, the last of which, "Elegy", is of exceptional beauty.

Belling married Miss Hannah Sewall, who died in 1926 without issue. He is survived by a brother, James Belling, residing in the Cheltenham district, also by a sister, Miss Annie Belling.

PROF. E. C. STARKS

WITH the passing at a comparatively early age of Prof. Edwin C. Starks, American ichthyological science has suffered yet another grievous loss, following, as it does, close upon the deaths of David Starr Jordan, Charles H. Gilbert, Carl H. Eigenmann and Barton Warren Evermann. Thus, within a comparatively few years the five zoologists, who, with Theodore N. Gill (1837–1914), may be said to have dominated the study of fishes in the United States during the last half century, have died.

Prof. Starks was born at Baraboo, Wisconsin, on January 25, 1867, studied at Stanford University from 1893 until 1897, and was then appointed assistant to the United States Biological Survey. From 1899 until 1901 he held the position of curator and assistant professor of zoology at Washington (Seattle). In 1901 he returned to Stanford University, being appointed curator in 1901, assistant professor in 1908 and associate professor in 1927.

A list of Starks's published works on fishes, including those in which he collaborated with Jordan, Gilbert and others, would contain some seventy or more titles. Many of these were of a systematic nature, and included the results of an ichthyological survey about the San Juan Islands, Washington, the fishes of Panama Bay (with Gilbert), and the fishes of Puget Sound (with Jordan). In collaboration with Jordan he was responsible for an important series of revisions and monographs of Japanese fishes published between 1901 and 1906. By far the most valuable of his contributions to ichthyology, however, were the series of papers dealing with the osteology and affinities of various groups of bony fishes. These papers, with their careful descriptions and well-drawn illustrations, furnish a monument of accurate and painstaking research, and are invaluable to students of fish taxonomy.

J. R. N.

WE regret to announce the following deaths:

Prof. E. W. Hobson, F.R.S., formerly Sadleirian professor of pure mathematics in the University of Cambridge, on April 18, aged seventy-six years.

Sir Edward Rigg, C.B., C.V.O., who was appointed assistant assayer in the Royal Mint in 1873 and was superintendent of the Operative Department from 1898 until 1918, on April 14, aged eighty-three years.

News and Views

Rubber Industry Bill

IN the House of Commons on April 11, Mr. H. Williams asked the president of the Board of Trade whether he was aware that the Research Association of British Rubber Manufacturers had discharged many of its staff and suspended research work for lack of funds. (This matter was referred to in a leading article in our issue of February 11.) Mr. Williams asked further whether, in the circumstances, facilities would be given for further progress of the Rubber Industry Bill. Mr. Runciman stated that he was aware of the situation. He said: "The Government recognise that it is desirable that the work of this Association should continue and have decided to give an opportunity for further discussion in Parliament of the Rubber Industry Bill." Owing to pressure of business in the House of Commons, it is proposed to introduce the Bill at an early date in the House of Lords.

Improvement of Beef Cattle in Australia

IF, as predicted by Dr. J. B. Orr, Australia is to become "the stock farm of the Empire", one of its urgent needs is the improvement of the beef cattle breeds in the northern tropical parts of Queensland, North Australia and Western Australia. The handicaps to British breeds are sparse fodder and prevalence of ticks and tick fever. The success reported to have followed the introduction of Brahman (Zebu) strains into herds in poorly grassed, tick-infested territories bordering on the Gulf of Mexico induced the Australian Council for Scientific and Industrial Research in 1931 to make a close investigation of the actual position. As a result, it has for some time strongly advocated experimental breeding in Australia to evolve a suitable cross for the north between British and Brahman cattle. Lack of funds prevented immediate action, but four pastoral companies have now made sufficient money available to ensure a thorough test of the possibilities of the cross. An officer of the Council is in the United States selecting suitable animals (probably eight bulls and two cows) which will be shipped to Australia and, after compliance with exacting quarantine conditions, will be divided amongst the properties of the companies, which at present carry chiefly shorthorns and Herefords. All breeding and culling will be under the sole supervision and control of the

Commonwealth Council for Scientific and Industrial Research. Many years will be required for the evolution of an animal suitable for northern tropical conditions but success, if attained, will be of considerable importance to many parts of the Empire.

Coloration Problems in Animals

ALL who are concerned with the problems raised by the coloration of animals will be interested in the announcement that two hog-deer (*Cervus porcinus*) have just been born at the Gardens of the Zoological Society of London. This animal, of about the size of a roe-deer, has a more or less conspicuously spotted coat in the summer, and one of a uniform brownish hue speckled with white in the winter. But the young are heavily spotted, as with our fallow and red-deer, the spots serving to form a 'concealing' coloration. Another coloration problem, and in a way yet more interesting, now presents itself in the sixteen flamingoes just purchased and sent to the Society's park at Whipsnade. These birds lose much of the brilliance of their pink coloration in captivity. Careful note should therefore be made of the intensity of pigmentation of the new arrivals. It has been stated that birds in the London Gardens recovered their lost brilliance when they were turned out into a paddock affording free access to a large pond, well-stocked with small crustaceans. In the gardens of the New York Zoological Society an interesting experiment was made, years ago, on the beautiful rosy flamingo (*Phœnicopterus ruber*) which, in successive moults during captivity, became paler and paler, and finally almost white. By mixing a harmless dye with the food the fading process was considerably lessened, while some retained their original full colour for years. What was the 'harmless dye', and was it continuously administered? Under the more favourable conditions at Whipsnade, perhaps these birds may breed. In this event a valuable opportunity will be furnished to mark the effect, if any, of climatic influence, and food, on the coloration in their progeny.

Australian Sector in the Antarctic

THE Australian National Research Council is very much gratified at the announcement that an Order in Council has been issued by the British Government affirming that His Majesty the King has sovereign rights over the antarctic territory, other than Adelie Land, south of lat. 60° S., between long. 160° and 45° E., and placing such territory under the authority of the Commonwealth of Australia from the date on which the necessary legislation is passed by the Commonwealth Parliament. Seven years ago, during the presidency of Sir David Orme Masson, the Research Council urged that sanction be sought for Australian administration of that part of the continent between long. 160° and 90° E. The matter was discussed at the Imperial Conference in 1926 when it was placed on record that there were certain areas to which British title existed by virtue of discovery. More thorough exploration of this 'Australian sector' was, however, obviously desirable and to that end the Governments of Great Britain, Australia and New Zealand, with liberal financial aid from Sir MacPherson Robertson of Melbourne, fitted out the "Discovery" expeditions under Sir Douglas Mawson in the seasons 1929–30 and 1930–31. These explored the greater portion of the sector between long. 160° E. and 45° E. including Enderby Land, Kemp Land, Queen Mary Land, King George V Land and new areas to the east of Kemp Land which were named MacRobertson Land and Princess Elizabeth Land. Australia will now presumably assume a measure of responsibility for developing and regulating existing and possible industries in the sector, including the enforcement of the International Convention on Whaling.

International Cloud Photography

THE intensive international study of meteorology during the Second International Polar Year, 1932–33 includes also the sky, and General Delcambre, president of the International Commission for the Study of Clouds, selected two periods for specially detailed investigation in France and neighbouring countries. The first was on April 12 and 13, while the second is arranged for July 12 and 13, 1933, and General Delcambre has asked for material from England. Should conditions on July 12 and 13 be suitable, meteorologists with cameras are asked to take at least three cloud photographs each day, as near as possible to the hours of 8 a.m., 2 p.m. and 7 p.m. B.S.T., and others at intermediate hours whenever the general character of the sky changes. The purpose of the photographs is to represent the changes of the sky as a whole, and cloud-systems should be photographed rather than individual clouds, using, for preference, a wide-angle lens. Artistic merit is a secondary consideration; the prints should show as much detail as possible, but should not be re-touched. Filters should be used if necessary to bring out the structure. It is important that the following information should be given on the back of each print: name and address of the photographer, place where taken, date and time. It is desirable also that notes should be added as to the fraction of the sky covered by cloud, the nature of the clouds in the part of the sky not included in the photograph, the direction in which the camera was pointing and the approximate elevation above the horizon. Prints, suitably packed, should be addressed to: M. le Ministre de l'Air, Office National Météorologique, 196 rue de l'Université, Paris 7, and in the corner should be written "Année des Nuages".

Trevithick Centenary Commemoration Programme

THE centenary commemorations of the death of Richard Trevithick will be held on April 22, 23 and 24. On Saturday afternoon, April 22, a demonstration will be held at Camborne, where Trevithick made his first experiments with a steam road carriage, and on Sunday afternoon a memorial service will be held in the Tregajorran Methodist Chapel, in the parish of Illogan, Cornwall, his birthplace. On Sunday morning a memorial service will be held at 11 a.m. in Dartford Parish Church, Kent, where the preacher will be the Right Rev. the Lord Bishop of Rochester. At the close of this service an address on Trevithick will be given by Mr. L. St. L. Pendred, and a wreath will be placed on the memorial which recalls Trevithick's death at the Bull Inn, Dartford, on April 22, 1833. At evensong at 3 p.m. in Westminster Abbey on Sunday, special reference will be made to the centenary by the preacher, the Ven. Archdeacon V. F. Storr, and at the end of the service a chaplet will be placed beneath the Trevithick window in the north aisle of the Abbey. Finally, on Monday, April 24, at 6 p.m., a memorial lecture will be delivered by Prof. C. E. Inglis, at the Institution of Civil Engineers, Great George Street, S.W.1, by kind invitation of the Council. The chair will be taken by Sir Murdoch Macdonald.

Unemployment and the Schools

At the National Union of Teachers' annual conference on April 15 the new president, Mr. H. N. Penlington, of Hemsworth, Yorkshire, opened his address with the declaration that unemployment is the outstanding problem of our age; and this *leitmotif* dominated the rest of his discourse under the headings of school objectives, school buildings and school staffs. With the ever-increasing displacement of human labour by machinery, leisure seems destined to bulk more and more largely in human life, and it follows that preparation for life must increasingly include equipment for commendable uses of leisure. Unemployment in the building trade could be substantially relieved by carrying into effect school building programmes in respect of more than fourteen hundred schools which are admittedly insanitary or in other ways totally unfit for their purpose. Not less urgent is the need of relief of overcrowding of classes, in nearly eight thousand of which the enrolment exceeds fifty pupils. Meanwhile, the number of unemployed teachers grows and is expected to reach between two and three thousand by September next. If the school-leaving age should remain unchanged, the number of 'school-leavers' this year will be about half a million—an exceptionally large number—and a large proportion of these must go to swell the numbers of the unemployed. The time is opportune, Mr. Penlington suggested, for raising the school-leaving age, and he emphasised the dangers of an unenlightened and reactionary policy spreading discontent, already rife, on account of the 'cuts' in the Burnham scales.

Herrings and the Origin of Petroleum

It would seem at first a far cry from a modern herring catch to petroleum genesis, but a recent discovery off the coast of Alaska proves this to be by no means the case. Some twenty or thirty years ago a boat loaded with herrings was wrecked off Admiralty Island, Alaska, and recently samples of the sea deposits, near to where the wreck occurred, were dredged up and sent to the United States Geological Survey in order that an analysis could be made of an unusual waxy substance which they contained. The investigation was in charge of Dr. R. C. Wells of the Survey, who proved that the wax was a complex compound formed of decomposition products of the fat in the fish, combined with calcium and magnesium salts of the sea-water. It was further found that high-temperature distillation of this wax gave rise to an oil having affinities with petroleum. In all theories of organic origin of petroleum the most difficult part to understand is precisely how the original substance underwent conversion into the hydrocarbon oil which we recognise in crude petroleum and, while we may visualise the environment under which these changes took place, the actual chemical mechanism involved is far more difficult to conceive.

As a report issued by Science Service (Feb. 14) states in connexion with this matter, the fact that the fatty acids formed by decomposition of the fish united into a complex waxy salt with minerals in the sea-water suggests that something of the same sort may have happened in the ancient seas in which petroliferous deposits have been laid down. The only criticism we have to make in this instance is that practically all scientific evidence available tends to show that the time factor is of fundamental importance in the production of petroleum, quite apart from the environment in which it may have been conceived. In this particular illustration, it would seem that comparatively little fundamental change could have taken place in the organic substance deposited by this wreck, and we question whether the results of distilling this wax-like material are really indicative of more than would be expected from interaction between animal substance and sea salts, interactions which must, in point of fact, be constantly in process in every sea and in all kinds of environments.

Mechanical Transport in India

During the last forty years, railways have been a great boon to India, but now their practical monopoly is being seriously challenged by vehicles propelled along roads by internal combustion engines. The paper read to the Indian Section of the Royal Society of Arts on March 10 by Col. F. P. Barnes on the development of mechanical transport is therefore a timely one. He computes that the number of motor vehicles in India is about 160,000 and is rapidly increasing. But this only gives 1 vehicle for every 2,000 inhabitants. This compares with 1 in 5 in the United States and 1 in 32 in Great Britain. There is thus plenty of room for development. Amongst the advantages of motor transport are that it employs a large number of people, it adds to the amenities of life and has a civilising effect. It now gives employment to about 200,000 people in India. Instead of using the tonga and bullock wagon, the business man uses a car and can cover a much larger area in a much shorter time. He can also send his family to the hills in comfort. The civilising effect is shown in Waziristan, where a great circular road has been constructed running through a country of tribesmen who, a few years ago, were formidable enemies of the British. The road was largely constructed by men who had fought against the British and some of them are now employed as policemen to patrol it. Many passengers now leave their rifles at home, showing that law and order is being established. Col. Barnes pointed out the great advantages that would accrue to the railways if the motor industry were developed so as to feed and not to compete with them. Mechanical transport in India has received little encouragement from the Government. It has been mainly regarded as a source of extra revenue and heavily taxed. Despite this, it has flourished and is now one of the principal industries in the country. There can be little doubt that if it is encouraged, there will be a great future in India for mechanical transport.

Meteor Crater, Arizona

THE *Meccano Magazine* for March contains an illustrated article on this unique formation. The photographs give a vivid idea of the force of the impact, which shattered the rocks, and forced up great blocks of limestone. Mr. D. M. Barringer has for many years been making efforts to discover the meteor itself. Two vertical shafts were sunk near the centre of the crater, but there was no success, and the work was impeded by the influx of water, which turned the powdered rock-flour into a quicksand. Eventually experiments on the impact of projectiles led to the conclusion that oblique impacts give a nearly circular depression; Mr. Barringer had at first assumed that the meteor would lie under the centre of the pit, but further examination of the shattered rocks suggested that it had come from the north and was likely to lie under the southern edge of the pit. A shaft is now being sunk in undisturbed soil a quarter of a mile to the south of the pit; this will be continued to a depth of some 1,400 ft., and then a horizontal shaft will be run to the north, in the hope of encountering the meteor, which may be either a single great metal mass (in which case it is estimated to weigh some ten million tons) or a compact swarm of smaller masses. There is still some trouble from water, but it is hoped to overcome this by surrounding the shaft with reinforced concrete. Mr. Barringer has now been carrying on his arduous exploration for many years, and certainly deserves success. The article makes some estimates as to the date of the impact; it cannot be less than seven centuries ago, from the evidence of old trees growing on the rim; and it is thought to be less than five thousand years ago, from the fact that little erosion of the scattered blocks has taken place. Also the native Indians have a vague tradition of a fiery descent from heaven. Probably it may be dated between one and two thousand years ago.

Mind as a Living Process

THE second of the L. T. Hobhouse Memorial Trust lectures was given by Dr. Charles S. Myers on May 19, 1932, and has been published under the title of "The Absurdity of any Mind-Body Relation" (Oxford University Press. 2*s*. net). Dr. Myers maintains the view that any relation between mind and body is absurd because mental activity and living bodily activity are identical. The mechanical principles of the natural sciences are only an abstraction from the quasi-dual set of principles—direction and mechanism—that govern the entire universe. Each is an abstraction from the whole activity. Mind and life are identical properties of living matter, which differs from lifeless matter in its inherent, purposive, self-directive, and finally purposeful struggle for existence. From this point of view then, the hypotheses of psycho-physical parallelism, of interactionism, and of either form of monism are untenable. Dr. Myers quotes with approval from Hobhouse to the effect that life arose not from dead elements, but from pre-material elements which also gave rise to inanimate matter, so that all life contains a germ of mind. Mind is thus to be regarded as the expression of the directive activity of living matter. This directive activity is to be regarded as the highest unitary activity of the nervous system: the lower directive activities may not always be in harmony with the highest and hence the mental conflicts, conscious and unconscious. Dr. Myers discusses the relation of the cognitive, affective and conative aspects of experience and the part played by instinct and intelligence. The point of view is most lucidly expressed and raises interesting questions for philosophy, psychology, biology and physical science. It is worthy of note that ancient and medieval thought realised the problem also, and that only from the context in many writings can one know whether the word 'anima' is to be translated life or mind.

Origin of the Irish Flora and Fauna

IN his presidential address delivered last November to the Royal Irish Academy, Dr. R. Lloyd Praeger returned to a subject which has occupied his attention for forty years—the problem of the Irish flora and fauna (*Proc. Roy. Irish Acad.*, **41**, 125). The problem has been much discussed, but always with an obscurity of background due to absence of fossil evidence which might give the clue to the routes and periods of past immigrations. In such circumstances conclusions assume a personal interpretation and Dr. Praeger's view is that much of the present flora and fauna reached Ireland over land-surfaces, either during inter-glacial (Aurignacian) times, or in the same way after the ice had finally passed away, or probably during both periods. Certain plants and animals found with these immigrants, including the American and probably the Lusitanian element, are older than these, and survived the main glaciation. These oldest elements migrated northward in pre-glacial times along the western European coast line, or eastward from America when the intervening barriers of sea were at least much less formidable than they are at present.

Migration of Red Grouse

THE University of Aberdeen inquiry into the movements of the red grouse would welcome the co-operation of owners or tenants of grouse-moors willing to ring young or adult birds during the present season. Rings, with instructions for their use, may be obtained from Prof. James Ritchie, Marischal College, Aberdeen.

Economic Minerals

THE third number of *Sands, Clays and Minerals*, a new quarterly magazine devoted to economic minerals, contains a series of articles covering a varied and attractive field. Particularly noteworthy is a paper on British coals by Mr. A. L. Curtis in which a wealth of interesting information on the origin, composition and classification of coals and related materials, such as graphite, jet and peat, is gathered together. This is effectively illustrated by a beautifully produced coloured plate showing typical hand-specimens of fourteen of the materials dealt with. Other articles describe raw materials such as sands, tripoli powder, and sapphire (with two plates of rough and cut stones); research methods involving the application of ultra-violet light, elutriation, magnetism and heavy liquids; the mining of china clay, the properties of refractory cements, the decay and restoration of building stones, and the sources and uses of tantalum and niobium. The magazine is likely to be of great service to technical and commercial men who are interested in mineral products but may not have the time or opportunity to follow the more specialised literature. It is published by Mr. A. L. Curtis, Westmoor Laboratory, Chatteris, the annual subscription being 5*s*.

Researches on Cacao

THE first annual report on cacao research in 1931 carried out by the Imperial College of Tropical Agriculture, Trinidad, has just been published. Founded in 1922, the first years of the life of the College were necessarily occupied in academic duties, and although cacao was included in the scheme for long-range research work in 1927, it was not until 1930, when contributions from the cacao-producing Colonies and some of the manufacturers in Great Britain allowed of the purchase of a small estate and the recruitment of three special research officers, that any large development in this side of the work took place. The report deals with the results of the first year's investigations and it is a tribute to the College that so much fundamental information should have been gained in such a short time. On the botanical side, the problem has been approached from three main aspects, namely, propagation studies, genetical survey and studies of fruitfulness, and it is proposed to continue the work on similar lines in the future. The chemical and ecological section has begun an environmental study of the cacao tree and has carried out a soil survey of the Gran Couva district with a view of determining how soil types and environment affect productivity. Both growers and manufacturers alike should profit from the improved yield and quality in the crops, which there is every hope will result from these investigations. The report, price 1*s*., may be obtained on application to the Editor of *Tropical Agriculture*, Imperial College of Tropical Agriculture, Trinidad, British West Indies.

Deaf and Dumb in England and Wales

THE National Institute for the Deaf has issued a memorandum commenting upon a report by the late Dr. Eichholz to the Minister of Health and the President of the Board of Education on "A Study of the Deaf in England and Wales, 1930 to 1932". It is considered that the proposals contained in the report are inadequate to meet the needs of the deaf and dumb and of those who become deaf through disease or accident. Disappointment is expressed with regard to some of the proposals, and suggestions are made which it is considered would better the position, though it is realised that it may be impossible at present to incur fresh expenditures upon the work necessary to ensure the well-being of these classes.

Bibliography of Earthquakes

THE Dominion Observatory at Ottawa has continued its useful work by publishing a list of one hundred memoirs on earthquakes received during the third quarter of 1932. With very few exceptions, the memoirs belong to the last two years. All the principal countries in which earthquakes are studied are well and uniformly represented, a result that is no doubt due to the appointment of collaborators in Italy, France, England, Canada, Japan and Germany, as well as in various parts of the United States.

New Air Speed Record

WARRANT OFFICER FRANCESCO AGELLO, of the Italian Air Force, set up a new air speed record on April 10, when he attained an average speed of 423·76 miles an hour. Agello was flying a Macchi-Castoldi 72 seaplane at Desenzano, Lake Garda, and it is stated that on one run he reached a speed of more than 430 miles an hour. The machine was one of those originally intended for the Schneider trophy race of 1931. The previous record, 408 miles an hour, was set up on September 29, 1931, in a Vickers-Supermarine *S 6B* seaplane flown by Flight-Lieut. G. H. Stainforth.

New Director of the U.S. Bureau of Standards

IT is announced by Science Service, Washington, D.C., that Dr. Lyman J. Briggs has been appointed director of the U.S. Bureau of Standards, in succession to Dr. G. K. Burgess, who died on July 2, 1932. Dr. Briggs has been chief of the Division of Mechanics and Sound of the Bureau since 1920. He has carried out much research on aerodynamics, gyroscopic stabilisation and properties of liquids. He is the co-inventor, with Dr. Paul R. Heyl (also of the Bureau of Standards), of the earth inductor compass that is now widely used in aircraft. For this invention, Drs. Briggs and Heyl shared the Magellan fund and medal, awarded by the American Philosophical Society for "the best discovery or most useful invention relating to navigation, astronomy, or natural philosophy".

Sectional Meeting of World Power Conference

THIS year the World Power Conference sectional meeting will be held in Scandinavia, on June 26–July 8. Everyone interested in the energy problems of large industrial undertakings is cordially invited to take part. The Conference opens at Copenhagen on June 26. The members next proceed to Stockholm by special sleeping-car trains, where the opening address will be given by the Crown Prince of Sweden. A number of very attractive tours has been arranged, including one to Finland by aeroplane or boat. The closing session will be held in Oslo on July 8. The Conference Bureau will assist those who desire to pay a visit to any holiday resort. A large number of rooms have been reserved in the smaller hotels at prices which are stated to be far below the usual Continental level. The exchange also is in favour of sterling. Further details can be obtained from the offices of the World Power Conference, 63 Lincoln's Inn Fields, London, W.C.2.

Fifth Pacific Science Congress

AT the invitation of the Government of Canada and under the auspices of the Canadian National Research Council, the Pacific Science Association will hold the fifth Pacific Science Congress, for the study of Pacific problems, in Victoria and Vancouver, B.C., Canada, on June 1–14. It is expected that some thirty countries bordering on the Pacific Ocean will be represented at the Congress by four to six hundred men of science. The president of the Executive Committee of the Congress will be Dr. H. M. Tory, president of the National Research Council of Canada and director of the National Research Laboratories. The Congress will open at Victoria on June 1, where sessions will be held until June 3. On June 4, it will proceed to Vancouver, where further sessions will be held until June 14. A post-Congress tour has also been arranged from June 14 until June 19, when it will terminate at Calgary. The Congress will work in two divisions: Biological Sciences, under the chairmanship of Prof. C. McLean Fraser, professor of zoology at the University of British Columbia, Vancouver, and Physical Sciences, under the chairmanship of Prof. R. W. Brock, professor of geology and geography at the University of British Columbia. The secretary of the Congress is Mr. S. J. Cook of the National Research Council, whose address, in connexion with the Congress, is Hotel Vancouver, Vancouver, B.C., Canada.

Announcements

THE King has been pleased to appoint Sir William Cecil Dampier, fellow and sometime senior tutor of Trinity College, Cambridge, to be one of the Development Commissioners, in succession to the late Mr. Vaughan Nash.

BY an order of the Committee of Privy Council, Sir Thomas Lewis, director of the Department of Clinical Research in University College Hospital, London, has been appointed a member of the Medical Research Council in succession to Prof. J. J. R. Macleod, regius professor of physiology in the University of Aberdeen.

THE Melchett Medal for 1933 of the Institute of Fuel has been awarded to Sir John Cadman, chairman of the Anglo-Persian Oil Co., Ltd., and the Iraq Petroleum Company. The medal is an annual award for "original research or professional, administrative, or constructive work of an outstanding character, involving the scientific preparation or use of fuel."

IN view of certain changes in the administration of the Ministry of Agriculture of Brazil, the Directoria de Meteorologia will henceforth be entitled the "Instituto de Meteorologia, Hidrometria E Ecologia Agricola". Mr. R. P. Xavier retired from the position of director of the Brazilian Meteorological Service on March 6, and has been succeeded by Mr. C. de A. Martins Costa.

IT is announced by the Paris correspondent of the *Times* that the French Government has created a chair of mathematical physics at the Collège de France for Prof. A. Einstein. Special legislation was necessary and a Bill was prepared by the Ministry of Education and passed rapidly through the necessary stages in the Chamber of Deputies before the Easter recess. A few days earlier, the Madrid correspondent of the *Times* stated that the Spanish Minister of Education had announced the acceptance by Prof. Einstein of a chair in Spain and that, while the Government had made no precise conditions, it was thought Prof. Einstein would go to Madrid.

THE forty-fourth Congress of the Royal Sanitary Institute will be held at Blackpool on June 17–24, under the presidency of the Right Hon. Lord Cozens-Hardy. The Congress will be divided into the following sections: Preventive Medicine; Architecture, Town Planning and Engineering; Maternity, Child Welfare and School Hygiene; Veterinary Hygiene; National Health Insurance; Hygiene of Food. Conferences of representatives of sanitary authorities, medical officers of health, engineers and surveyors, sanitary inspectors and health visitors will also be held in connexion with the Congress. Particulars can be obtained from the secretary of the Institute, Mr. J. W. Dudley Robinson, 90, Buckingham Palace Road, S.W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A junior assistant in the surgical unit of the Welsh National School of Medicine (University of Wales), The Parade, Cardiff—The Secretary (April 25). A lecturer in civil engineering and building at the Portsmouth Municipal College—The Registrar (May 5). A dairy bacteriologist in the Department of Agriculture and Horticulture of the University of Bristol—A. W. Ling, Agricultural Advisory Office, 22, Berkeley Square, Bristol 8 (May 6). An assistant lecturer in engineering at the Cardiff Technical College—The Director of Education, City Hall, Cardiff (May 6). A lecturer in electrical engineering at the Chelmsford School of Art and Technology—The Clerk to the Governors (May 8). A lecturer in pathology to dental students in the University and pathologist to the Queen's Hospital, Birmingham—The Secretary, The University, Birmingham (May 15). A demonstrator in physiology at St. Thomas's Hospital Medical School (University of London)—The Dean of the Medical School (May 27).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Remarkable Optical Properties of the Alkali Metals

I DESCRIBED in the *Philosophical Magazine*, about fifteen years ago, the high transparency for ultra-violet light of thin films of sodium and potassium, deposited by condensation at liquid air temperature, and their complete opacity for visible light. A resumption of the work has brought out some extraordinary properties.

A film of potassium, several wave-lengths in thickness, through which the sun is quite invisible, transmits about 25 per cent of the light included in the spectrum range 3000–1860 A.; the reflecting power from 3000 A. to 2700 A. is about 75 per cent, which means that practically no energy is absorbed, thick and thin films having equal transmitting power in this region. Below 2700 A. the reflecting power falls off very rapidly, soon reaching a value less than that of the bulb of fused quartz. But the most remarkable property is that interference bands are found in the spectrum of the reflected light. An end-on hydrogen tube was used as a source, and the film thickness increased by small steps, a spectrum being taken for each thickness. The dark bands entered from the short wave-length side and accumulated in the spectrum, orders so high as the fifth recording before the opacity became too great.

The filament of a tungsten lamp was invisible through a film which gave only two orders, the transmission of visible light being less than 1/100,000. Films of more than double this thickness gave very distinct interference bands, which means that the ultra-violet light, after two transmissions through the film, has still sufficient intensity to interfere with the light reflected from the first surface. The interference bands cannot be driven into the region above 2700 A., as the reflecting power of the first surface is too high to permit of interference, the bands being found only in the region of low reflectivity. In this region potassium has optical properties resembling those of selenium and the aniline dyes, the conducting electrons appearing to be without influence.

It seems probable that it will be possible to determine the dispersion in this region by the direct observation of the Brewsterian angle of polarisation, and experiments are now in progress along this line. All the alkali metals have now been examined, the transmission region moving down the spectrum as we pass from cæsium to lithium.

With cæsium the transmission band begins at about 4300 A., the films appearing of a blue-violet colour by transmitted light, of a purity equal to that shown by a strong solution of cuprammonium or dense cobalt glass. The film thicknesses are being determined by depositing a circular patch on the inner wall of a bulb, measuring its opacity to visible light and then opening the bulb and determining the amount of metal by titration with phenolphthalein. Experimental determinations of n and κ by the customary methods of metal-optics will be commenced shortly for the region of high reflecting power.

In the earlier work, it was reported that these films were unstable at room temperature, breaking up in a few minutes into globules and becoming almost perfectly transparent. I now find that if the quartz bulb is thoroughly out-gassed before the metal is distilled into it, the potassium films are permanent for several days, especially if moderately thick. A thin-walled quartz bulb with such a film makes a very useful filter for spectroscopic work; the sun's disc is invisible through it, yet we can photograph the solar spectrum through it with an exposure of only about four times normal exposure, the spectrum extending from a little above H and K to the extreme end. The transparency of such a film is nearly uniform as far down as the aluminium line 1862 A., and the lower regions are now being examined with a vacuum spectrograph.

R. W. WOOD.

Johns Hopkins University,
Baltimore.
March 20.

March 28.—Supplementing my letter of March 20 on the remarkable optical properties of the alkali metals in the ultra-violet region, I am now able to state that my prediction that potassium would show a Brewsterian angle of plane polarisation in the region below 2700 A. has been verified. The angle found for 2500 A. was 37°, which makes the refractive index $n = 0{\cdot}75$. I am not yet sure how accurately the angle can be determined, or how complete the polarisation is, but the intensity ratio of the two images obtained with a quartz Rochon prism was 1 : 120. The images had equal intensity in the visible and near ultra-violet.

Total reflection is thus to be expected for angles of incidence greater than 50°. This too was verified, at least in part, though I have not yet secured a sharply defined angle. At normal incidence the reflection at wave-length 2200 A. is of the order of 2 per cent, and the first few photographs taken indicate that a rather high value sets in for angles greater than 45°—though the increment seems to be gradual as the angle increases above this value. Better results are expected when more nearly plane reflecting surfaces are secured.

The angle of polarisation shows thus far no evidences of dispersion, which is perhaps to be expected, as the dispersion of the metal in the visible region is extremely small, as shown by Duncan, from measurement of principal incidence angles and azimuths.

Interference maxima and minima up to the fifth order appear in the spectrum of the reflected light between $\lambda = 2100$ and 3000 (not 2700 as reported in my earlier letter).—R.W.W.

Absorption Spectrum of Vitamin A at Low Temperatures

WE have been trying to devise more precise physical criteria for the recognition of biologically important molecules. Obviously, the only ultimate test for such a molecule is its action on living organisms. Physical tests can, however, be used as a guide to decide whether it is worth while to apply biological tests.

The physical criterion which has proved most valuable in this field is the absorption spectrum of the complex molecules, but this has nearly always been measured in solution at ordinary temperatures, and has usually given broad structureless bands which frequently appear similar for different molecules.

At low temperatures the bands of many molecules develop a structure with a considerable amount of detail[1], since (i) the ground-states of the molecules are simplified by the elimination of all but those of lowest energy, and (ii) the blurring caused by the molecular fields of neighbouring molecules is reduced as these become quiescent. Both effects tend to *diminish the width of the absorption bands* and to bring out details of structure which cannot be recognised at atmospheric temperatures. These structured bands can be used as a much more definite discriminant than the continuous bands obtained at ordinary temperatures.

Thus, in the case of carotene dissolved in ethyl alcohol, the visible bands at

4790, 4440, and 4200 A.

become sharper and are displaced to

4990, 4670, and 4350 A.

whilst a fourth band appears at 4060 A. On the other hand, the ultra-violet band at 2700 A. becomes narrower, but it is not displaced and develops no structure.

This method of analysis has been used to discriminate between vitamin A and the product, giving a band near 3280 A., obtained by irradiating carotene[2] with the mercury line Hg 2650, under conditions which probably permitted the access of traces of oxygen. The two physical tests for vitamin A (the absorption band with its maximum at 3280 A. and the development of a blue coloration with antimony trichloride) did not discriminate between these two materials; but we now find that when concentrates of vitamin A are cooled to the temperature of liquid air, the maximum at 3280 A.* is displaced to 3350 A. and that new bands are developed at

2900, 2770, 2580, 2510, and 2430 A.

The last three were of low intensity. Identically the same structure was found in a B.D.H. concentrate and a concentrate from turbot liver oil, prepared by Dr. T. Moore. The detailed structure may conceivably be due to an impurity associated with vitamin A, but this difficulty cannot be completely excluded from any spectroscopic observations not made upon pure substances.

When the product obtained by irradiating carotene is cooled, the band near 3280 A. breaks up into a series of bands at

3780, 3570, 3410, and 3210 A.

The more precise spectroscopic test therefore shows definitely that the molecule produced by irradiating carotene is different from that associated with the band at 3280 A. in vitamin A concentrates.

We propose to extend this method of investigation, by cooling with liquid hydrogen in order to develop more fully the fine structure of the absorption bands of complex molecules.

F. P. BOWDEN.
S. D. D. MORRIS.
C. P. SNOW.

Physical Chemistry Laboratory,
Cambridge.
March 22.

---

* A faint subsidiary maximum at 3100 A. was also observed at ordinary temperatures for all the concentrates examined.

Cultivation of Parasitic Nematodes

THE following is an outline of a method of obtaining large numbers of the larvæ of nematodes parasitic in sheep in media the composition of which can be much more accurately controlled than any that have hitherto been used. Experimental work on these organisms should throw light on the physiology of nematodes and be of great assistance in the treatment and control of these parasites.

(1) Obtain eggs from the fæces, or contents of the large intestine of sheep, by placing these in a cone shaped sieve and passing water through this into a large jar, stirring all the time. Allow the contents of this jar to settle, pour off the fluid, and repeat two or three times. Mix a portion of the final sediment with an equal quantity of a solution of sugar 1 lb., water ¾ pint, formaldehyde 1 per cent. Fill a narrow-mouthed vessel rather overfull with this and cover the top with a large cover-slip, taking care that there are no air bubbles left. After 12 hours or so, remove the cover-slip, and wash off the eggs floated up on it to a clean tube[1].

Another method is to obtain female worms from the fourth stomach and intestines of sheep, and to set free the eggs by breaking up the worms in a mortar with a little water. By this method the easily-obtained species *Graphidium strigosum*, common in the stomach of English wild rabbits, or *Trichostrongylus retortæformis* in the duodenum, give excellent cultures. Eggs obtained in this way do not hatch so well, probably because fewer are mature.

(2) Wash the eggs in a centrifuge three or four times in sterile water to remove sugar solution and debris.

(3) Treat for 30 minutes with 5 per cent Antiformin in 10 per cent formaldehyde[2]. Experiments are being done here on various other and less drastic antiseptics.

(4) Wash six times in sterile distilled water.

(5) Sow the eggs into sterile Petri dishes in which is a layer not more than 3 mm. deep of plain broth 1 part water 10 parts. Simpler media are now being devised.

(6) Inoculate each dish with a loopful of *B. coli*. It is possible that the larvæ will not develop on some strains of this organism. The strain used in this laboratory has been obtained from the intestines of the parasitic stages of the larvæ themselves.

(7) Leave the dishes at 18°–20° C. preferably in the dark or in the shade. Third stage infective larvæ, enclosed in their characteristic loose sheaths (which are the cast skins of the second stages which have not been thrown off) will be present in 6–10 days. The hatching of the first stage larvæ can be quickened by incubating the cultures, but this may also cause too rapid a growth of the *B. coli* and is not necessary.

Thousands of free-living stages of the larvæ can be so obtained and should be excellent subjects for experimental work. The number of larvæ obtained is limited only by the number of eggs used.

(8) The first parasitic stages can be obtained by placing the third stage larvæ in a 1 in 20 dilution of 'Milton'. They ex-sheath in 20 minutes or less at laboratory temperature. Stronger solutions damage or kill the larvæ. Other solutions containing hypochlorite will also induce ex-sheathing, but I have found the above to be best, because it remains stable, and ex-sheathed larvæ will live three or four days in the dilution of 1 in 20. Hypochlorite appears to be essential, chlorine failing to cause ex-sheathing.

(9) This 'Milton' solution also sterilises the larvæ

and kills the *B. coli*, so that these first parasitic stages can be put into sterile media, of whatever composition the worker desires.

(10) More than two hundred media have so far been tried in attempts to cultivate these ex-sheathed larvæ further, but so far no method has been found of inducing them to cast the next sheath and so become fourth stage larvæ. Experimental work is needed to find out the conditions required for this.

It is impossible in a brief letter to indicate the innumerable problems which have arisen during the working out of this method, but I should be glad to supply further details to anyone interested. There are also many interesting problems for the study of which the 'adult' nematodes parasitic in sheep might be used, rather than such relatively specialised species as *Ascaris*.

Anode Spot in a Neon Tube

WHILE studying the phenomena of the moving striation and anode spot in a discharge tube filled with neon, our attention was directed to the fact that the anode spot is intermittent in its emission, with a rhythmic fluctuation in its intensity.

A photograph taken by a falling plate camera is reproduced in Fig. 1, while Fig. 2 shows another plate taken in a similar way but with the portion near the anode more magnified. In Fig. 1, + and − denote anode and cathode respectively, which were about 17·5 cm. apart. The discharge tube was a straight one 4 cm. in diameter. It was filled with pure neon at a pressure of a few centimetres and was excited by a 2 kw. direct current generator giving 1,200 volts, the current in the tube being 190 ma. T.M. are the time marks, with an interval of 1/800 sec.

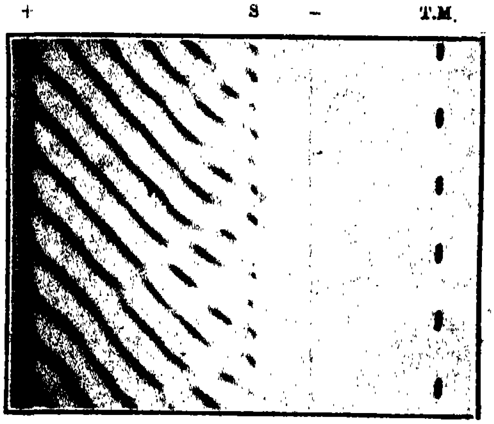

FIG. 1.

As will be seen in Fig. 2, the image of the anode spot, which was single in this case, is discontinuous in its emission. In fact, we see a series of luminous dots gradually increasing in its intensity, until, near the maximum intensity, one layer of the moving striation is detached from the anode and proceeds toward the cathode. The process is repeated at an interval of about 1/1160 sec. In the case shown in Fig. 1 the velocity of the moving striation, at the middle of the positive column, is about 30 metres per second.

Another point of interest seen in Fig. 1 is the rhythmic fluctuation in the intensity of each of the moving striations. Apparently, the intensity of each stria decreases as it approaches the cathode, until it begins to appear on the plate as discontinuous strips. Near the end of the positive column, a small luminous sphere is seen which is detached from the uniform positive column. The luminosity of this sphere (marked S in Fig. 1) is also found to be intermittent, with an interval of 1/1880 sec.

The remarkable regularity in the arrangement of the strips in Fig. 1 would seem to suggest that there may be an interference between the moving striæ and some kind of disturbance regularly coming against it from the cathode.

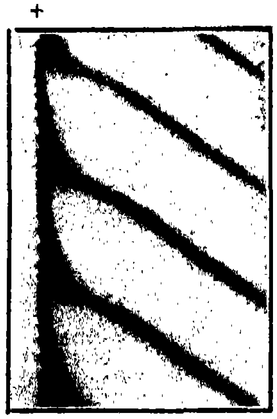

FIG. 2.

As the anode spot is in fact the starting point of the moving striation, the closer investigation of its change with time may be of significance in the study of discharge through gases.

The details of the experiment will be published in the Scientific Papers of this Institute.

Rôle of the Solvent in Electrolytic Dissociation

IN a recent paper[1] Sir Harold Hartley and Mr. O. L. Hughes bring forward evidence for the view that "solvation (of ions) is a *statistical* process, the relative amounts of the two kinds of molecules (in non-aqueous solutions containing small quantities of water) being roughly proportional to the concentrations in which they are present in the solution". This view is supported by the work of Butler[2], who found that, although lithium chloride in alcohol-water mixtures is solvated preferentially by water, solvation by water is not an exclusive process.

Sir Harold Hartley goes on to interpret the degree of association of electrolytes in terms of (1) the size of the solvated ions, considered as rigid structures the motion of which obeys Stokes's law, and (2) the distance of approach of oppositely charged ions below which, according to Bjerrum's formula[3], the number of ion-pairs (consisting of solvated ions) increases rapidly.

In the light of the aforementioned ideas about solvation, is this treatment free from objection? On the statistical view of solvation, the solvent shell around an ion cannot be a rigid structure. An individual solvent molecule can leave it and its place be taken by another molecule or perhaps by an oppositely charged ion. Consequently the solvent shell of an ion does not act as an impenetrable barrier to other ions and undissociated molecules of the kind which occur in vapourised strong electrolytes at temperatures such as 2,000° C. can be formed. The size of the solvated ion is not of prime importance. The deciding factors are the free energies of the systems (1) cation and anion solvated to average extent and (2) undissociated molecule, possibly solvated as well. That solvation of an undissociated molecule may be a factor comparable with solvation of an ion can be shown by an approximate calculation for a dipole similar to that of Born for an ion[4].

The larger ionic radius in non-aqueous media often given by Stokes's law[1,5] may be due to the solvent molecules being larger and hence the solvated ion larger, although the energy of solvation may be less than in water and the solvent shell may even contain a smaller number of molecules.

Dimensions of Fundamental Units

PROF. CRAMP has proposed[1] that the dimensional expressions for the electrostatic and electromagnetic units may be simplified by regarding quantity of electricity Q as fundamental. To my reply[2], that including Q would cause confusion because, whereas M, L and T are quantities which vary with the velocity of the observer, Q is invariant, Prof. Cramp's[3] rejoinder is the question: How it is known that Q is invariant? The invariance of the charge carried by a moving particle is, I believe, generally accepted. A simple proof of the consistency of this invariance with the special principle of relativity is given in N. R. Campbell's "Modern Electrical Theory", p. 361.

Prof. Stansfield[3] makes a plea for the simplification introduced by regarding k and μ as mere numerals. I agree with Prof. Stansfield, but in order to make this point of view logical, I think that we must regard 'magnetic pole', m, as a unit derived from 'electric charge', Q, rather than as an independent unit.

The hypothesis tentatively accepted in physics is this, that there are in the physical world two fundamental factors, namely, positive charges ('protons') and negative charges ('electrons'). Each of these is a symmetrical radial field of unlimited extent. The lines of flux of the proton are directed radially outwards, those of the electron radially inwards. The lines possess 'tension' and also 'mass per centimetre', the magnitudes of which agree (in analogy with $v = \sqrt{F/m}$ for the transmission of transverse disturbances along a stretched string) with the fact that transverse disturbances are transmitted along the lines with the velocity, c, of light. Fluxes similarly oriented show mutual lateral repulsion; those oppositely oriented show attraction. Vectorial combination of fluxes permits the resultant forces to be expressed in terms of the tensions in the lines. When electric fluxes are in relative motion, laterally, the 'charges' from which they emanate exert mutual forces on account of this relative motion, namely, the charges are mutually repelled when their laterally approaching fluxes are oppositely oriented, and are mutually attracted when the fluxes are similarly oriented. Experiment shows that the magnitude of these forces depends on the relative lateral velocity of the fluxes.

In empty space the law of force between charges Q and Q^1, at rest, d cm. apart, is $f = Q \times Q^1/d^2$. Usually, however, the space is not empty but contains some medium, that is to say, it contains protons and electrons. These exert forces on Q and Q^1 and the resultant apparent mutual force between Q and Q^1 is not $(Q \times Q^1)/d^2$ but is $(Q \times Q^1)/kd^2$, where k is a *numeral* intended to take account of the 'nature of the medium'.

The force between charges, resulting from relative lateral motion of their fluxes, involves Q, Q^1 and d and, in addition, the velocity of relative lateral motion. This force is called 'magnetic'. Its value, for two moving fluxes due to charges in empty space, involves only Q, Q^1, d and the relative velocity v of lateral motion of the fluxes, but in space which is not empty but contains a medium, the apparent mutual force between Q and Q^1 is due, partly, to the action on the fluxes of Q and Q^1 of the fluxes due to moving protons and electrons in the medium.

A 'unit magnetic pole' is a fictitious thing. There are no known means of producing such a field of flux as a unit pole is imagined to produce. The notion of such a pole is useful, however, because we can produce by means of currents (that is to say, by moving charges) effects (locally) such as poles ought to produce. This means, I think, that we assume the meaning of the equation $f = (m \times m^1)/\mu d^2$ to be the same as that of the equation $f = (Qv \times Q^1v)/\mu d^2$ where μ is a numerical constant taking into account the presence of moving charges within the medium, and v is the relative velocity with which two like charges must move past each other in order that their 'magnetic' repulsion shall equal their 'electrostatic' repulsion. Experiment has shown that this velocity is c, the velocity of light.

If then we write Coulomb's laws, $f = (Q \times Q^1)/kd^2$ for charges and $f = (Qc \times Q^1c)/\mu d^2$ for magnetic poles, we find that the nature of a charge, Q, may be expressed either as $k^{\frac{1}{2}}df^{\frac{1}{2}}$, using the E.S. system of units, or as $\mu^{\frac{1}{2}}df^{\frac{1}{2}}c^{-1}$, using the E.M. system, the ratio of the two expressions being c, the velocity of light.

From this simple point of view, which I think is sound, we must regard both k and μ as mere numerals, and 'pole', m, not as an independent unit but as equivalent to the product $Q \times c$. Always we measure a thing by its effects. Charge has two ways of producing the same effect. A charge Q at distance d from a like charge repels that charge *electrostatically* with force f if the charges are at rest, or *magnetically* with the same force f if the charges have relative lateral motion of c cm. per second.

Boundary Tides in the Kattegat

In order to facilitate observations on the vertical movements of the boundary surface far from the shore a recording boundary gauge has been constructed. A commercial steel barrel of about 200 litres capacity used for kerosene was provided with an axial tube of two inches width running through the barrel and having its ends welded to the flat ends of the barrel. Thick glass rings inserted at both ends of the tube serve to reduce friction against a vertical guide, 25 metres in length, of phosphor-bronze wire rope, which runs straight through the tube. The wire rope has its upper end attached to a large buoy, which is kept five metres below the surface by means of a double anchorage[1], a heavy weight attached to the wire rope at its lower extremity keeping it vertical and well stretched. The barrel is thus free to move in a vertical direction between depths of 6 and 30 metres.

The barrel, filled partly with large spherical glass floats, partly with fresh water, was hermetically closed and finally balanced with the recording instrument and with an additional load, so as to be in equilibrium in sea-water of the density 1·022. This is the average density of the water at the boundary surface in the central Kattegat, where two or three such instruments were kept anchored during several weeks of the fall of 1932. By means of a precision pressure gauge attached to the barrel, its varying depth, which may be taken as equal to the depth of the boundary, is recorded on a large drum turned by clockwork, which runs for three weeks or more. An automatic record of the boundary waves is thus obtained, which it would otherwise require continuous hydrographic soundings from ships anchored at the points of observation to realise. Moreover, the boundary gauges also draw their records under weather conditions which would make observations from anchored ships impracticable.

The records prove that very considerable wave-like movements of the boundary round its average depth at about 17 metres were going on the whole time the instruments were working. The total depth at the anchored systems varied between 40 and 60 metres. Waves of a semidiurnal period between 11 and 13 hours from crest to crest, with a maximum height of about 6 metres, were conspicuous in the diagrams. These waves attained their largest amplitude about full moon and new moon, but there were also considerable variations in amplitude apparent over shorter intervals of time.

A harmonic analysis carried out on a fortnight's record gave an amplitude of the semidiurnal lunar tide in the boundary of ± 0·6 metres (the M_2–component tide), and of the semidiurnal solar tide ± 0·2 metres (the S_2–component tide). The surface tides in the Kattegat are much smaller; thus at Varberg the amplitude of M_2 in the surface is ± 0·038 metres and of S_2 ± 0·01 metres. The amplitudes of the tidal components in the boundary brought out by analysis, however, only account for a fraction of the maximum height of the boundary waves in our records.

Boundary waves of semi-diurnal period were first discovered in the Great Belt in 1907 by Otto Pettersson and have since then been recognised at other localities and also in the open sea by other observers. Local variations in the amplitude of the waves revealed by our records seem to support Zeilon's theory, that topographical features of the sea-bottom play an important part at the generation of the boundary waves.

It is of interest to note, that 'inertia currents' similar to those found from current measurements in the central Baltic (see the accompanying letter by Gustafson and Kullenberg), appear also to influence the boundary movements in the Kattegat. An analysis of one of our curves carried out with periods varied by steps from 13·9 to 14·5 hours gave a very distinct maximum of amplitude ± 0·3 metres for the sine curve with a period of 14·3 hours, which is equal to 12 pendulum hours at the latitude of the anchored systems : φ = 57° 15′ N. Analysing shorter fractions of 6 × 14·3 hours, the amplitude of the same sine curve occasionally rises to ± 0·7 metres, and the phase as well as the amplitude undergoes irregular variations, such as may be expected from waves set up by extraneous forces.

It is suggested that boundary gauges of the type here described suspended from ships, either drifting or at anchor, may be used for the study of such short period boundary waves, as were observed in the central Atlantic Ocean during the *Meteor* expedition.

Inertia Currents in the Baltic

Theoretically, a particle moving without friction on the surface of a rotating planet should describe a circular path in the course of twelve 'pendulum hours', that is, with a period given by $T = \frac{\pi}{\omega \sin \varphi}$ where ω is the angular velocity of the rotation and φ is the latitude. It is generally assumed, that these movements are insignificant compared to the currents actually existing in the ocean.

In the course of Swedish investigations on the downward spread of the wind-current, carried out by means of recording current-meters suspended from large buoys, which were kept well below the surface by means of double anchorage, currents, apparently of the inertia type, were recorded near the surface in the central Baltic, lat. 56° 44′, long. 19° 37′, depth of observation 17 metres, total depth 136 metres. Beside a current of nearly steady direction set up by the wind, there was a current component turning clock-wise at the rate of 24° 6′ an hour. This rate remained practically constant for several days, so that altogether fifteen revolutions were made in about eight days. A strong wind blowing for some thirty hours in the middle of the observations produced a change of phase in the rotation, but the angular velocity before and after the break remained the same.

When the residual current was strong, the rotating current caused periodic variations in its velocity and direction, but when it was weaker than the rotating current, as was generally the case, the resultant current described spirals, which soon approached to an almost circular movement.

The period of the rotating current is on an average 14½ hours, whereas 12 pendulum hours at this latitude amount to a value slightly less or 14·3 hours. Measurements at different depths, from 11 to 22 metres, and at different points in the same locality, gave practically the same results.

A natural interpretation of these results would be, that in the Baltic, where tidal movements are very small, the wind current, as the wind abates, gradually degenerates into a circular, or rather a spiral, movement of decreasing amplitude, the diameter of the paths of the water-particles varying from some 3 kilometres downwards. It appears likely, that similar 'inertia currents' are also to be found in the sea, at least where the tidal movements are not too strong to obscure them completely. An examination of current-records from the west coast of Sweden is being undertaken with this purpose.

Factors Controlling Date of Spawning in Frogs

In Nature of April 8, p. 521, reference is made to the factors which determine the time of spawning of the common frog, *Rana temporaria*.

Through the courtesy of the Royal Meteorological Society, I have been enabled to utilise the voluminous data contained in the Society's Phenological Reports for the investigation of this matter. The results, it is hoped, will shortly be ready for publication, but since the matter has now been raised, it may be of interest to state briefly that frogs are scarcely at all affected by the weather at the time of spawning, or that immediately preceding, but there is a close relation between the mean temperature over a long period prior to spawning and the mean date of spawning in a district. For example, within fifty miles of London, only a few cases of spawning usually occur in February, and March is the usual spawning month, most reports being about the middle of the month. I have calculated a correlation co-efficient of $-0\cdot77$ between the mean temperature at Kew for *February* and the mean spawn date for the area. The effect of March temperature is perceptible if one employs a weighted mean, allowing for the distribution of the spawn dates over the period, but it is much smaller. The only important effect of the weather at the time of spawning seems to be the break in the normal sequence of spawning caused by a very cold 'snap'.

Early History of the British Solomon Islands

Several references were made in the Calendar of Geographical Exploration published in Nature last year to the Solomon Islands, and the following notes on their early history may be of interest.

The Solomon Islands lie some five hundred miles east of New Guinea and were discovered on a voyage from Callao, Peru, in 1568 by the Spaniard, de Mendaña. After naming most of the larger islands during a six months' cruise, the two frigates returned to South America.

Mendaña named the islands after King Solomon with the idea of attracting colonists to search for gold and treasure. However, it was not until thirty years later that a second expedition of four ships set sail but failed to find the Solomons proper, arriving instead at Santa Cruz Island to the east, where a brief settlement was made until Mendaña's death in October 1595. The survivors (only three ships arrived) under the Portuguese navigating officer de Quiros made an attempt to reach San Cristobal, previously discovered in 1568. Not only were they unsuccessful in locating it, but they also failed to strike any land before the Philippines, whence they sailed for Peru.

For nearly two centuries nothing was known of the Solomons until Capt. Carteret in the *Swallow* rediscovered Santa Cruz and Malaita in 1767, without however landing anywhere. Next year came the French navigator de Bougainville, followed by de Surville (1769), Maurelle (1781) and Shortland (1788).

The climax of eighteenth century navigation was the shipwreck of two frigates under La Perouse which reached Vanikoro, Santa Cruz, in 1788, but about which nothing was known for forty years until Dillon, in command of the East India Company's *Research*, found proof in 1827 of their fate.

By this time whalers and traders, the latter in search of bêche-de-mer, sandal wood and tortoise-shell, had already begun the nineteenth century commercial exploitation of the tropics.

A New Alloy, 'Stainless-Invar'

Invar, *invented* by Ch. Ed. Guillaume *in* 1896, has a small coefficient of thermal expansion, about $1\cdot2\times10^{-6}$. Since then, no better invar has been obtained. I have, for the last six years, been engaging in the investigation of alloys having a small coefficient of expansion and obtained in June, 1929, an alloy[1] containing about 63·5 per cent iron, 31·5 per cent nickel and 5 per cent cobalt, which has a smaller coefficient of expansion than that of fused silica.

Several explanations of the small expansibility of invar have been proposed, but none can be considered to be satisfactory. I also tried to explain this phenomenon and developed a new theory[1] by which the small expansibility of invar can be satisfactorily explained from magnetic data. Following up this theory, I began to investigate the thermal expansion of the ternary alloys of iron-cobalt-chromium and found that an addition of a small quantity of chromium to iron-cobalt alloys containing more than 50 per cent cobalt considerably reduces their expansibility. In July, 1931, I obtained an alloy having a much smaller coefficient of expansion than that of fused silica. For example, the coefficient of linear expansion at ordinary temperature of an alloy containing about 36·5 per cent iron, 54·5 per cent cobalt and 9 per cent chromium is less than 10^{-7} in the annealed state, and that of another alloy having a very similar composition *to the above has* even a negative coefficient amounting to $-1\cdot2\times10^{-6}$. These alloys are so resistant to corrosion that polished surfaces can be left for several months in a moist atmosphere, water, sea water, etc., without showing any rust spots; they have been called 'stainless-invar' (Hakar Masumoto).

Research Items

Ethnology of Manihiki and Rakahanga, Cook Islands. Te Rangi Hiroa (Dr. P. H. Buck) has published as a separate monograph (Bull. 99, Bernice P. Bishop Museum), that part of the material collected by him on the Cook Islands expedition which was derived from the two atolls Manihiki and Rakahanga. The special interest of this investigation lies first in the fact that the people of the two atolls were one, passing as a body from one atoll to the other when forced to migrate by the depletion of the stock of coco-nuts and taro, until 1852 when the practice was stopped, owing to the loss of life in transit, and the community split into two; and secondly, because the original settlers were a single biological family—a fact which has had a marked effect on social organisation and tradition. According to tradition, the atolls were discovered by Huku of Rarotonga, who later settled his sister and her husband Toa on them. No priests came with the settlers; and in consequence the traditions and mythology are defective, the genealogical records poor in extent and detail—the primary parents are not remembered—and for seven generations the people had no gods. Family genealogies give a period of about 550 years from the first settlement, this agreeing with the date of the last migration to New Zealand. Owing to the peculiar circumstances of the settlement, Toa, in order to secure a male heir, married each of his four daughters and his granddaughter in succession, sons being born of the last two unions only. Male descent is all-important in the succession to rank and title, otherwise descent is bi-lateral; but more importance is attached to male descent, unless the mother comes of the more important lineage. After the people had been without gods for seven generations, two gods were introduced from another island.

Bitumen in Embalming. From the time of Herodotus onwards, the tradition has been that the Egyptians made use of bitumen, mainly from Judæa, in embalming; but since 1908, Mr. A. Lucas, of the Government Laboratories, Cairo, has contended in a series of papers that bitumen did not come into use for this purpose before the time of the Ptolemies, and that even though it might have been used for this purpose then and afterwards, he had found no evidence of it. For his evidence he relied on solubility tests and on sulphur content, in which Judæan bitumen is high, as well as characteristic smell, fluorescence and the colour and appearance of substances extracted by solvents. Dr. Percy E. Spielmann has now applied the tests of fluorescence and spectroscopic analysis of the ash to certain samples (*J. Egypt. Arch.*, 18, pts. 3–4). While bitumen gives no trace of fluorescence, samples of resin show colours averaging round a strong yellow ochre. In the spectroscopic analysis, vanadium and nickel, accompanied by molybdenum, were the predominant components in the bitumen ash; but on the other hand the resins show only the faintest trace of these metals, so that they could be used for detecting the presence of bitumen. When applied to Egyptian material—from a cranial cavity (Ptolemaic), a head (Ptolemaic), and bones from the junction of ribs and spine—it was found that there was strong evidence, with certain reservations, for the presence of bitumen in two of the three samples examined. A similar examination made with wood-tar, a material the presence of which Lucas had definitely identified, suggested that the metal-free wood-tar would be just the substance to act as a diluent for both the bitumen and the resin, thus accounting for their presence in embalming material in relatively low proportions. It seems clear, however, that bitumen was used in embalming, mixed with wood-tar and resin.

Vital Capacity and Occupational Characteristics. "Physiological Standards and Occupational Characteristics of Bodily Functions of the Japanese" by Tomoyosi Isikawa (Reports of the Institute for Science of Labour, Kurasiki, Japan) gives the results of measurements of vital capacity in nearly 8,000 Japanese ranging from four to eighty-two years of age. The aim of the investigation was to obtain some standard of physical fitness as an aid to vocational guidance. A modified Hutchinson's spirometer was used for measuring the children and students, and Verdin's centilitre spirometer was used for the adults. Vital capacity in the Japanese appears to increase rapidly up to sixteen years of age and then rises slowly to a maximum between 25–29 years in males and 30–34 years in females. Compared with some European and American data, the Japanese, especially the women, have a low vital capacity. The average measurement for 875 males aged 15–81 years was 3,213 c.c. while for 562 females aged 15–71 years the mean was only 1,964 c.c. Some attempt was made to assess vital capacity in various types of occupation but in most instances the numbers in the groups were too small to give any reliable figures. There is some indication that those engaged in light or sedentary work tend to have a low vital capacity. Dr. Isikawa would be well advised to refer to English reports on vital capacity by Greenwood, Newbold and Cripps in which the difficulties of establishing a standard of physical fitness are carefully discussed. These authors concluded that the inherent variability of vital capacity, even within homogeneous groups of apparently healthy persons, is so great that the fixation of a normal standard is impossible.

Californian Sponges. Mr. M. de Laubenfels has recently described the sponge fauna of the western coast of the United States (*Proc. United States Nat. Mus.*, 81, No. 2927, Art. 4. Smithsonian Institution, 1932). Six out of a hundred and one species discussed are new and three new genera and five new varieties are established. Very little literature on Californian sponges has been published, therefore this work is specially welcome, containing as it does, in addition to the systematic parts, extensive notes taken in the field whenever possible on the living sponges. To mention but a few of these interesting observations there is the description of *Spheciospongia confederata* de Laubenfels, the largest sponge in the world (the author having frequently found examples nearly a metre across and mentioning a definite record of one of nearly three metres), and remarkable for its changes of colour when transferred from its original habitat. *Mycale bellabellensis* (Lambe) is also very large, funnel-shaped with a height of at least 100 cm. and a diameter of 122 cm. Many of the species are beautifully coloured, rich brown, red, yellow and blue when alive. In one case at least the deep blue colour is due to symbiotic organisms in the ectosomal regions. A species of *Gellius* grows abundantly on the floor of a cavern just below low tide, a most unusual habitat.

Phylogeny in the Genus *Oenothera*. Since the investigation by de Vries of feral *Oenothera Lamarckiana* in Holland the genus of the evening primroses has been studied from many points of view in Europe and in the United States. Prof. R. Ruggles Gates (*J. Linn. Soc. Bot.*, **44**, 173; 1933) considers the evolution of the section *Onagra*. A table of the known North American species is given and another summarises investigations of the genetic complexes and chromosome catenations in those species which have been cytologically examined. It is suggested that the subgenus *Onagra* was derived from the large-flowered subgenus *Raimannia* in Central America and that a series of dominant mutations occurred as the genus spread northwards with the retreat of the ice at the end of the last ice age. Interspecific crossing played an important part in the development of the subgenus, as a result of which most of the species are permanent crypthybrids composed of two complexes and breeding true because of catenation (linkage of their chromosomes) during meiosis. Hybrid vigour may well have led to survival and spread of such species. There is evidence that dominant mutations giving rise to smaller flowers have appeared independently and successively in different parts of the Continent from different lines of descent. Species and varieties with cruciate petals constitute another series of independent parallel mutations. It is urged that while interchange of segments between non-homologous species (internal hybridisation of Lotsy) will account for the appearance of a certain number of new types, its value as an evolutionary factor is limited in comparison with the importance of interspecific crossing and the regular occurrence of gene mutations in the hybrid swarm. Two new species are described and figured.

Age of the Andes in Ecuador. A paper on "New Fossil Fresh Water Molluscs from Ecuador" (*Proc. U.S. Nat. Mus.*, No. 2946; 1932) by W. B. Marshall and E. O. Bowles deals with a collection made by Dr. George Sheppard in the Cuenca district of Ecuador, and it includes three new genera, each represented by a new species. The genera have been named *Sheppardiconcha*, *Potamolithoides* and *Ecuadorea*. In regard to the age of these fossils, all of which are of fresh-water habitat, the authors conclude that it "cannot be later than Pliocene, and it may be earlier". According to Dr. Julia Gardner, the discovery of these fossils in the Azogues Sandstone of Ecuador is "apparently a confirmation of the theory indicated from an earlier collection from Peru that the ancestors of the recent fauna of the lower La Plata are to be found near the headwaters of the Amazon, where they lived before the divide between the Amazon and the La Plata was established". The discovery of late Kainozoic fossils in the sediments of this interandine region of Ecuador proves the existence of a continental facies of the Kainozoic rocks in this part of the world, which is almost certainly homotaxial with the marine beds of the coast-belt, and assists in the elucidation of the many tectonic problems which are associated with the uplift of the Andes in the same region. As the Azogues Sandstone, the principal formation occupying the Cuenca Basin, and in which the fossils above referred to were found, are folded into fairly steep and symmetrical anticlinal folds with a north and south trend, it is apparent that this structural movement must have post-dated the age of the included fossils of the stratified deposits, and hence may be post-Pliocene.

Humidity Tables. Messrs. Negretti and Zambra have recently placed on the market for the price of 3*s*. 6*d*. a set of tables of relative humidity for use with artificially ventilated wet and dry bulb hygrometers. The range of temperature is from 100° F. to 212° F. Dry bulb readings are set off on the left hand side of the table in steps of 2° F., and the depression of the wet bulb to the right, also in steps of 2° F. The tables are printed on both sides of a celluloid tablet which measures about 5 in. × 3½ in. There is a leatherette case to protect the tablet from damage when not in use. The figures have been derived from centigrade tables published by the National Physical Laboratory and these have been extrapolated to give a greater range. This completes a series of four similar sets of hygrometer tables, two on the Centigrade scale, with upper limits of 50° and 100° C., and two on the Fahrenheit scale, one ranging from 20° F. to 120° F. and the other, as described above, from 100° F. to 212° F. They agree closely with the Assmann and the U.S. Bureau of Standards Humidity Tables. The arrangement of the figures is convenient, and the printing is not only very clear on the sample specimen but is also deep enough to ensure continued clearness even with constant use. At the highest temperatures on the Fahrenheit scale a depression of the wet bulb of 78° is provided for, the corresponding relative humidity at 194° F. being so low as 11 per cent.

X-Ray Investigation of the Copper-Aluminium Alloys. A. J. Bradley and Phyllis Jones have re-examined (March meeting of the Institute of Metals) this system using the powder method. They confirm that the body-centred β-phase cannot be retained by quenching, and show that, contrary to the opinion of Obinata, a homogeneous β′-structure is invariably produced, which appears to be closely related to that of the face-centred α-phase. Alloys quenched in the γ-range are indistinguishable from the δ-alloys. Up to 19 per cent aluminium, the structure of δ-CuAl is essentially of the γ-brass type, photometer measurements leading to the formula Cu_9Al_4. The modification of the δ-phase beyond 19 per cent noted by Westgren is confirmed. In this δ′-phase (19–22·5 per cent aluminium), the number of atoms in the pseudo-cubic cell falls from 52 to 49. On quenching a two-phase alloy with 22·8 per cent from 700° C., the single ε-phase is obtained, which appears to be cubic. Between this composition and 29 per cent of aluminium, the annealed alloys show many types of structure, the η-phase consisting, therefore, of a number of phases of small range of stability, or one or more of gradual modification. Friauf's structure for the θ-phase, $CuAl_2$, is confirmed and it is also confirmed that this phase has not a unique composition.

Wilson Photographs of Cosmic Ray Phenomena. A full account of the results obtained by Blackett and Occhialini with their cloud-chamber photographs of cosmic ray phenomena has appeared (*Proc. Roy. Soc.*, March). The experiment has been described in a letter to NATURE (130, 363, Sept. 3, 1932). The Wilson chamber is placed with its axis horizontal in a magnetic field of about 3,000 gauss, and the mechanism of the chamber is operated whenever there are simultaneous discharges of two Geiger-Müller counters placed above and below the chamber. Some of the photographs show single tracks passing through the chamber, but in many cases there are 'showers' of tracks numbering up to twenty or so. Similar showers have just been reported by Anderson (*Phys. Rev.*, March 1). Many of the particles appear to diverge from a single point inside or outside the chamber—in some cases ten or more such radiant points can be detected. Many of the tracks are not appreciably bent by the magnetic field; some tracks are apparently due to electrons, and others seem to require for their explanation a particle of approximately electronic mass with positive electrical charge. The direction in which the tracks are bent by the field indicates a positive charge if we accept very strong evidence of the direction of motion. The ionisation along the tracks is then found to be far too small for a particle having proton mass and charge and the experimentally found magnetic deflection ($H\rho$). The ionisation is comparable with that in an electron track of similar $H\rho$. The existence of a positive electron in cosmic ray track photographs, which has also been suggested by Anderson, is therefore very probable. The suggestion of the authors is that the positive and negative electrons are created by a collision process, and that they may perhaps be identified with the "quantum states of negative kinetic energy unoccupied by electrons" postulated by Dirac. These particles should have only a short life; they can be annihilated by a negative electron jumping into the unoccupied state, the energy being converted into radiation. The calculated lifetime of these positive electrons is not inconsistent with observing them in the cloud chamber. Protons and heavy particles generally seem to be infrequent and perhaps absent in the cosmic ray photographs.

Hydrogen Isotope. G. N. Lewis has described some preliminary experiments in which water containing a large proportion of the hydrogen isotope H^2 has been obtained (*J. Amer. Chem. Soc.*, March). When ordinary water is electrolysed, the heavy isotope accumulates in the residue, and water of specific gravity 1·035 was obtained, containing one-third of its weight of the heavy isotope. The refractive index of this water is considerably lower than that of ordinary water, and it is considered probable that the chemical properties of compounds containing H^2 will be very different from those of ordinary hydrogen compounds. Other communications from the United States show that measurements in the Bureau of Standards indicate that heavy water freezes when surrounded by melting ice, its freezing point being 0·05° C. above zero. Its boiling point is higher than 100° C.

Astronomical Topics

Nova of March 20. A preliminary announcement of the discovery of this nova appeared in NATURE of April 15, p. 553. Dr. Kukarkin, of Moscow, states in U.A.I. Circ. 434 that he has found three images of this star on old Moscow plates; on 1899 March 14 its magnitude was 14·1; on 1900 March 21 it was 13·8; on 1907 February 13 it was 13·0. Plates taken on the following dates failed to show the star (the figures in brackets after the dates show the limiting magnitudes of the plates): 1901 April 9 (14·5); 1903 April 16 (13·5); 1905 March 1 (14·1); 1905 March 27 (13·5); 1905 April 8 (14·8); 1907 April 5 (13·9); 1908 January 3 (16·0); 1908 March 29 (14·8); 1910 March 1 (14·5); 1911 February 21 (14·8). Dr. Kukarkin suggests that it is a variable star of the U Geminorum type; it may have a period of about a year, but there must be some irregularity in it. The decline must be very rapid; Dr. Delporte notes in U.A.I. Circ. 434 that plates taken on March 25 and 29 go down to mag. 17·5, but there is no trace of the nova.

The Gegenschein or Counterglow. The German astronomer, Theodor Brorsen, discovered this faint patch of light opposite to the sun in the year 1855. It is difficult to observe, and can only be seen in perfectly clear air free from all glare of terrestrial lights, and when it does not fall on the Milky Way. A bulletin issued by Science Service, Washington (Feb. 11), describes a study of it made recently by Dr. C. T. Elvey at the Yerkes Observatory; he used the 40-in. refractor and a photoelectric cell to measure the luminosity. Several series of measures of light were made along parallel lines running north and south, each long enough to cover the Gegenschein and the dark sky outside it. The measures, when reduced, were plotted; they exhibited the Gegenschein as an oval area, its length along the ecliptic being 22°–35°, and its breadth in latitude 21°–26°. These dimensions are about twice as great as the area that was visible to the unaided eye. The integrated luminosity was determined to be −0·28 magnitude, which is brighter than any of the stars except Sirius and Canopus; but being spread over a large area the intensity is very feeble at any point. The report states that "at the centre, where brightest, the intensity is equal to that of a star of magnitude 6·2"; this is, however, indefinite in the absence of indication of the size of the patch of light included. October and November were found to be favourable months for the study; the region being north of the equator, and away from the Milky Way.

The phenomenon is believed to be an extension of the zodiacal light, looking brighter than elsewhere owing to proximity to the earth, and the full illumination of the particles. It is conjectured that there may be an actual concentration of particles near the earth, describing periodic orbits under the combined attraction of sun and earth.

Ephemerides of Variable Stars. The Cracow Observatory undertook at the request of the International Astronomical Union the task of preparing yearly ephemerides of eclipsing variable stars. No. 11 has appeared, bearing the title "Rocznik Astronomiczny". It is edited by Prof. T. Banachiewicz, and contains ephemerides of 800 stars, and elements without ephemerides of 722 more. The book also contains tables of precession and obliquity, and predictions of occultations of stars by the moon for Cracow and four other Polish Observatories. The explanations are given both in Polish and in Peano's flexible Latin.

A supplement to the *Japanese Astronomical Herald*, vol. 25, contains observations of variables made in Japan in 1932, and predicted maxima of 90 long-period variables for 1933.

Structure of Cellulose

THE recent annual Convention of the Technical Section of the Paper Makers' Association of Great Britain was unusual in that the subject chosen was one which appeared at first sight to be more of academic than of practical interest. Fortunately, in the able hands of Prof. H. Mark, of the University of Vienna, who opened the conference, the subject lost many of its complexities, and technical men present were stimulated to attempt to apply theory to their practical problems.

Prof. Mark's paper, which is published in a special issue of the *World's Paper Trade Review*, dealt principally with the structure of cellulose. He supported the theory, now generally accepted, that cellulose is built up of so-called micelles consisting of bundles of parallel chains of glucose molecules, and he dwelt at some length on the controversy which at present concerns the actual length of these chains. The majority of the evidence, including that based on the chemical properties of cellulose, points to a length of 150–200 glucose units, and yet one cannot ignore the work of Staudinger on viscosity, which can only be explained by a much higher figure. It may be that the lower figure represents a minimum value.

In opening the general discussion, Sir William Bragg referred to the X-ray evidence on which so much of this work is based. Subsequent speakers paid some attention to the much-debated question of the mechanism of the hydration which occurs when paper is beaten, and a suggestion was made that the resulting change in structure is analogous to that which occurs in the manufacture of true cellulose plastics by chemical reaction.

Prof. Mark also indicated how such theories might be applied to problems in the art-silk industry, although it seems that they can do little at present to explain what occurs when cellulose is beaten for paper-making, as this problem is concerned with water absorption rather than with modification of crystalline structure. When, for example, a silk fibre is bent, the outer layers are stressed more than the inner core, and so long as the elastic limit of the latter is not surpassed the fibre will return to its original position and will thus show resistance to creasing. Unfortunately, this resistance is usually decreased when a fibre is treated so as to increase its tensile strength, but it is now possible to obtain the core more highly orientated than the surface and so to preserve both properties. Here one can take a leaf from the book of Nature, since this difference in orientation is already present in the natural silk fibre. If, however, the silkworm is placed on a revolving rod, and is therefore compelled to spin more rapidly, it descends to the level of human endeavour so far as lack of creasing-resistance of its product is concerned.

Prof. Mark obviously voiced the opinion of those present when he stated that the interaction of water and cellulose is one of the most interesting questions in paper-making. He chose to approach the problem by taking absorption capacity as an index of changes produced in the area and quality of the surface of the fibre by chemical treatment or by beating. His results indicate that hydroxyl groups are responsible for the fixation of water molecules on the surface of the cellulose, and act by virtue of the secondary valencies of the oxygen atoms; treatment with a chemical reagent opens up small slits or holes in the micelle into which further molecules of water may pass. Penetrations of solvents and swelling agents into the cellulose lattice is not unknown, but as a rule X-rays show evidence of well-defined addition compounds. Until now, however, no one has succeeded in preparing a true cellulose hydrate, so that an important link in an otherwise strong chain of evidence is still missing.

Sunspots and Meteorological Phenomena

IN a monograph entitled "L'Influence Solaire et les Progrès de la Météorologie"[*] Henri Mémery advances the theory that sunspots show a tendency to increase and decrease at certain definite times of the year, and that this tendency is shown whatever period of years is considered. He suggests further that there is a relationship between the amount of sunspot development and numerous terrestrial disturbances, for example, spells of abnormal rainfall and temperature, and also between individual groups of sunspots and meteorological phenomena. Fifty years of solar and meteorological observations made at the Observatoire de Physique solaire et de Météorologie, Talence, provide a large part of the experimental data on which his views are based.

To most astronomers and meteorologists, the theory that sunspot activity shows any permanent relationship with the dates on our terrestrial calendar will probably appear a highly improbable one, to be accepted only in the face of overwhelming evidence of its truth. The evidence in this paper rests upon curves showing the average area on the sun's disc covered by sunspots on each day of the year for periods of 12, 41 and 50 years. There are, however, apparent discrepancies between the lengths of the periods implied by the statements made alongside these curves and those given above the curves. The periods are quoted as 12, 40 and 50 years in the latter case and it is possible that 40 should replace 41 in the algebraic expressions given below. It will be seen, however, that the conclusions reached are not affected by this uncertainty, nor even by the doubt as to whether the 12 year period should not have been taken as 13 years. Few would deny that the three curves show considerable similarity, but the periods covered are 1889–1901, 1880–1920, and 1880–1929, that is, the 12 years in the first group are used also in the groups for 41 and 50 years, and the overlap is even greater for the 41 and 50 year means.

The question arises whether the similarity in the curves cannot be explained simply by this overlap. Take the case of the curves for 12 and 41 year periods. The similarity between these is held to imply a positive correlation between the ordinates. The two variables are x_1, and $(12x_1+29x_2)/41$ where x_1 and x_2 are the means for the common period of 12 years and for the *remaining* 29 years of the 41 year period, respectively. The correlation between x_1 and $12x_1/41$ is of course unity, and, unless it is true that the shapes of the annual sunspot curves obtained by using entirely separate series of years are similar, the correlation between x_1 and $(12x_1+29x_2)/41$ will by a well-known statistical formula bear the same *ratio to unity* as does the standard deviation of $12x_1/41$ to the standard deviation of $(12x_1+29x_2)/41$. This correlation coefficient works out to $+0·38$.

---

[*] L'Influence solaire et les progrès de la météorologie : résultats de 50 années d'observations solaires et météorologiques comprenant les observations et les recherches effectuées à Talence à partir de 1900. Par Henri Mémery. Pp. iv+23. (Talence : Observatoire de Physique solaire et de Météorologie, 1932.)

The correlation coefficient between the 12 and 41 year mean curves was then determined, using the ordinates of the two curves at the beginning and middle of each month. The figure found was $+0·38$, that is, exactly that which is to be expected solely from the overlap. (The *exact* agreement between the two coefficients must of course be accidental. Had the experimental figure been even $+0·5$ or $+0·6$ the evidence that the overlap was not the cause of the similarity would still have been inadequate, but with a coefficient of $+0·8$ or more the author's claim would have been well supported.) A similar analysis could be applied to the other pairs of curves, but it has been deemed sufficient to show by a single random test that a faulty method has been used with misleading results. Although no further example of overlapping is evident in the comparative curves illustrating the other relationships claimed in this paper, the method adopted throughout has been to give purely statistical evidence for alleged physical relationships in such a way that a critical reader cannot see, until after considerable mathematical analysis of this evidence, whether the latter does in fact give any support for the supposed relationships.

It seems safe to conclude that most astronomers and meteorologists will not accept the author's ideas until more up-to-date statistical methods are used.

E. V. N.

Atmospherics Research in the Southern Hemisphere

A FEW years ago the Australian Council for Scientific and Industrial Research established a Radio Research Board to conduct scientific and technical research into some of the more fundamental problems associated with radio communication. Amongst the items of work which it was planned to carry out were the repetition of some of the investigations already in progress in Great Britain under the British Radio Research Board, with the view of obtaining a direct comparison of the propagation of electric waves in the two hemispheres. As a useful aid in this matter some of the investigators appointed in Australia had the advantage of receiving their training in radio research under the organisation in Great Britain. The results of the work already carried out in Australia are being published in a series of special reports, and the latest of these is entitled "Atmospherics in Australia (I)".* This report contains the results of observations made chiefly by means of two cathode ray oscillograph direction-finders supplied by the British Radio Research Station at Slough, where this type of instrument has been developed to a high degree.

The first series of observations were made on board the s.s. *Baradine*, in December 1929 and January 1930, when Messrs. Munro and Huxley were on their way to Australia to take up their appointments. After setting up the apparatus on board, observations were made on the transmissions from a number of European stations to enable a calibration curve to be obtained showing the error in apparent direction of arrival of the waves caused by the metal work of the ship. Regular daily observations on atmospherics were commenced one day before reaching Port Said and were continued during the remainder of the voyage. From the indications on the cathode ray oscillograph screen, both the true direction of arrival and the strength of each atmospheric was recorded. These observations, which were carried out on a wave-length of 30 km., supplied very definite evidence in favour of a thunderstorm origin for atmospherics. The directions, as recorded on the voyage through the Red Sea and across the Indian Ocean, converged on an area in Central Africa which is known to be the most active thunderstorm area in the world. Beyond Colombo, the directions of most of the other sources of atmospherics observed passed through other active thunderstorm areas in the East Indies and Northern Australia. Round the south coast of Australia, the predominant sources appeared to be within, or near to, the north of the continent.

On arrival in Australia, the apparatus used on the ship was installed near Melbourne for preliminary observations. Towards the end of 1930, a second cathode ray direction-finder arrived in Australia and was set up on a selected site about three hundred miles from the first instrument. The circuit arrangement of each instrument was modified to make the oscillograph unidirectional in its indications, and a short-wave wireless link was provided between the two stations so that simultaneous recording of the direction and intensity of individual atmospherics could be carried out; and such observations were commenced in March 1931. The majority of these observations were carried out on a wave-length of 3 km. as it was thus found possible to restrict the range from which atmospherics were received to about 2,000 miles, whereas on a wave-length of 30 km. the range was at least 5,000 miles. The origins of the atmospherics observed were located by taking simultaneous bearings at the two stations. Systematic observations taken in this manner on a wave-length of 3 km. showed that the range of intensities, when corrected for the distance travelled and the attenuation in the path, was quite small, being of the order of 4 to 1; and also that the intensity distribution about the mean was a normal probability one.

A large proportion of the atmospheric sources located were within the Australian continent itself. The small range of intensities noted above suggests a similar origin for all the atmospherics observed, and this has been confirmed by the correlation found between the indicated sources of the atmospherics and those of the thunderstorms located through the normal meteorological observation network. The authors conclude from their investigations that all the atmospherics observed had their origins in lightning strokes occurring generally in thunderstorms, or possibly, in a few instances, in dust storms. Observations of atmospherics have therefore been found to have definite meteorological value as they enable barometric depressions to be located and traced by observing the atmospherics which are generally associated with them.

---

* G. H. Munro and L. G. H. Huxley: "Atmospherics in Australia. (I)". Radio Research Board, Report No. 5. Melbourne. 1932.

Information on the diurnal and seasonal variation in the activity of atmospherics covering a period of more than a year is also given in the report. It has been found that the maximum activity of atmospherics occurs in the afternoon from 3 to 4 p.m. in any locality, although this maximum is less marked for sources over sea than for those over land. In Australia, atmospherics are very prevalent over the tropical areas in summer, but in winter, atmospherics arising within the continent are relatively few, those observed being associated with barometric depressions. Towards the end of 1931 two automatic directional recorders, of the narrow-sector type developed in Great Britain, were installed, and with the aid of these instruments more complete information on diurnal and seasonal variations is being obtained.

The report shows that this line of research has been satisfactorily established in Australia on a sound basis, and the results of the continuation of the investigation will be awaited with interest.

Hæmolytic Streptococci[*]

THE group of micro-organisms known as the hæmolytic streptococci is responsible for a number of acute inflammations in various regions of the body, such as erysipelas, heart disease, and puerperal fever, as well as for such diseases as scarlet fever and certain types of pneumonia. In addition, they are important secondary invaders, attacking those whose resistance is already lowered by some other infection. They spread in the body both by the lymph and the bloodstream and are frequently found on mucous surfaces in apparently healthy individuals. They are only known as parasitic upon the animal body and appear to maintain themselves in a human population like the meningococcus or pneumococcus, namely, by carriers.

Since these organisms are responsible for so many different diseases, it is of interest to inquire whether a particular variety of hæmolytic streptococcus is associated with each different disease. The late Sir Frederick Andrewes devoted seven years to the study of this problem and a report of the investigation, prepared for publication by his colleague, Mrs. Christie, and Dr. Christopher Andrewes, has now been issued.

The hæmolytic powers of *Streptococcus pyogenes*, the typical hæmolytic streptococcus, depend upon the production of a definite toxin which passes out into the medium and disintegrates the limiting membrane of the red blood cells: this soluble hæmolysin will pass through porcelain filters of the coarser type. The living organisms also reduce hæmoglobin or may convert it to methæmoglobin. As a method of separating the different types, it was soon clear that agglutination tests by themselves would prove of little value. It was necessary for an accurate antigenic analysis to carry out quantitative agglutin-absorption tests. Antisera were prepared by injecting an emulsion of the streptococci, killed by exposure to dilute formaldehyde in the cold for some days, intravenously into rabbits, on alternate days for about four weeks. The sera obtained had high titres. In carrying out a test, graduated doses of an emulsion of the organism are added to the same volume of serum. After standing overnight, the tubes are centrifuged and the clear supernatant fluid pipetted off and titrated, that is, its agglutinating power for the strain with which the serum was prepared, is tested. The closer in type the strain used for the absorption of agglutinin is to the latter, the less agglutinin will there be left unabsorbed, and vice versa.

The investigation has shown that these hæmolytic streptococci have such inherent powers of adaptation to their chemical environment as to make it impossible, for the present at any rate, to prepare a permanent systematic classification. The methods used for discrimination between forms of different origin may themselves change the characters of the organisms under observation. Only exceptionally are two strains serologically identical, but very rarely are they entirely dissimilar. In the case of scarlet fever, it appears that no one serological form can be credited as causal agent, though three or four recognisable serological types seem to be quite commonly found in it. An occasional representative of a scarlet fever group was found among the puerperal, surgical and erysipelas strains, but otherwise no distinct types stood out from this mixed group.

The general conclusion is that this group of organisms is in a state of constant flux in which it is difficult to find any firm foundation for a permanent systematic classification: success is probably unattainable by purely serological methods of investigation. The dangers of the hæmolytic streptococcus to human life appear to arise from this instability of behaviour: it has a special facility in adapting the refinements of its living chemistry to the particular host environment in which it finds itself. Progress would seem to lie in a deeper knowledge of the exact chemical events involved in this reaction between the host and the invading organism.

University and Educational Intelligence

CAMBRIDGE.—At King's College the following have been elected to fellowships: A. G. D. Watson, scholar and Harold Fry student of the College, and E. S. Shire, Reginald John Smith student and formerly scholar of the College.

THE use of sound films as an aid in the teaching of physical science is being tested in the University of Chicago with a series of twenty films of which the first two, entitled "Oxidation and Reduction" and "The Molecular Theory of Matter", have been produced under the supervision of the professors of chemistry and physics of the University. Three others on "Energy and its Transformation", "Electrostatics" and "The Velocity of Light" are in preparation. Similar series of twenty films each are to be produced dealing with biological science, social science and the humanities. The technical work is in charge of Erpi Picture Consultants and further particulars can be obtained (according to an article in the January issue of *School Life*) from the University of Chicago Press, 5750 Ellis Avenue, Chicago, Ill.

Calendar of Nature Topics

Varieties of Agricultural Crops

There is no simpler method of improving output than by sowing a good variety of seed instead of an inferior one. It is the first step in raising the standard of farming in new or undeveloped areas, and has given striking results when soil improvement by fertilisers would have been impracticable. Moreover, a new variety may enable the limitations imposed by climate to be overcome. A rapidly maturing strain of wheat extends the wheat area by making the most of a short growing period, a drought-resisting variety brings in areas of low rainfall. Choice of seed is usually the most practicable method of mitigating the effects of plant disease caused by fungus or insect pests; this is particularly the case with crops of low value per acre which will not bear the cost of spraying. Immunity of particular varieties to disease is very rare, but when it occurs, as for example to the wart disease of potatoes, it is exploited to the full. More usually it is a case of a more or less marked degree of resistance, and then the aim of cross-breeding is to unite the disease resistance of one strain with the valuable agricultural qualities of another. The problem is never a simple one, for very many attributes are involved. It is further complicated by the fact that resistance to one disease may be associated with susceptibility to another.

Much is being done in Great Britain to improve existing varieties and introduce new ones. With crops already highly developed, spectacular improvements are unusual; the gain in yield or quality is generally small and special field technique is required in order to establish the extent of the improvement, and the agricultural areas in which the new strain may be substituted for the older kinds. Stiff-strawed varieties of cereals, high quality wheat and barley, beetroots rich in sugar, mangolds of high dry matter content, have all been developed in this way. A special case of raising varieties to suit a particular environment may now be in sight. There is no shortage of potential soil fertility in the form of cheap synthetic nitrogen compounds. An outcome of this might be the development of varieties specially suited to unusually rich soil conditions and able to effect an economical conversion of mineral fertilisers into farm produce.

Potatoes in the Fens

Potato planting is now in progress in the great black plain south of the Wash, probably the most sharply defined agricultural area in England. Even the town dweller, as the train carries him through Ely, March, or Peterborough, can scarcely fail to realise that here is something quite distinct from the 'country' as is usually understood. At this season, we see on all sides the black soil laid up in ridges, the bright red farm-carts serving gangs of women with seed potatoes for planting, and the horse-drawn ridgers covering in three rows of sets at once. Those who regard farm work as a leisurely and ill-organised occupation, should spend a few hours on a fenland farm in mid-April. The work proceeds with astonishing smoothness and rapidity and a very high standard of workmanship is attained.

The black land is capable of growing good crops of potatoes on its own resources, but is considerably helped by superphosphate. Indeed, the fenland farmer must be the most systematic user of superphosphate in Great Britain, for many of them recognise no other manure.

Having got his potatoes in, the farmer's chief anxiety is the extent to which his crop will be reduced by 'blight' which, although controlled by spraying, may seriously damage the crop in certain seasons, and the price of potatoes in the following winter. These two considerations are not unrelated, however, for a reduced crop generally means higher prices, although not necessarily sufficient to compensate for the lower yield.

In spite of considerable fluctuations in returns, the potato crop has no serious rival in this district. Sugar beet affords a useful alternative, and is widely grown, and carrots, celery, and mustard occupy some potato land. Cereals are extensively grown to balance the acreage, and the straw, which is particularly luxuriant in this fertile district, finds a special use in covering potato clamps during the winter.

Sperm Whales in the North Atlantic

Sperm whales are now relatively scarce animals, and the experience of the modern whaling stations which worked from the northern and western islands of Scotland, was that few sperms were captured in these waters and that they were invariably solitary bulls, truants from the schools. But in the great days of whaling, there were recognised about a dozen 'whaling grounds' for sperms in the North Atlantic, visited by the whalers during fairly definite seasons. Sperm whaling was not a seasonal trade, as was the fishing of the right whale from British sea-ports, for the sperm whalers were fitted out for a voyage of from two to four years duration and caught whales wherever they could be got. Therefore the appearance of whalers year after year at a fairly regular succession of places suggests definite movements or migrations on the part of the whales. When Charles H. Townsend plotted on a world-map the positions and dates of captured sperm whales recorded in the hundreds of log-books fortunately preserved in New Bedford Public Library, U.S.A., he found that April marked the opening of sperm-whaling in the North Atlantic. With few exceptions, the records above lat. 25° N. point to the presence there of sperm whales from April to September; in the Sargasso Sea they occurred in the summer of the northern hemisphere; between lat. 25° N. and the equator they were taken mainly during the October to March season; and along the coast of South America and towards the Cape of Good Hope the catches were largely made during the same season—summer in the southern hemisphere.

Young Barnacles Change their Coats

In the seas of western Scotland, the latter half of March is marked by the appearance in the plankton of myriads of the nauplius larvæ of barnacles (*Balanus*)—about a month later than the corresponding event in southern England. For a time the larvæ may be so numerous as to form the predominant constituent of the plankton, suggesting that the countless barnacles which whiten shore rocks spawn profusely and almost simultaneously, to the immediate benefit of the many shore animals which feed upon such organisms. In April, and particularly in the latter half of the month, the nauplii moult for the last time and assume the new cyprid form, which soon attaches itself by head and antennæ and glues itself by secretion from the cement gland to rocks, stones, shells, piles of piers or whatever object may be on the spot. Then in this, which Darwin called the "pupa stage", some of the juvenile structures are lost and the free-swimming larva is transformed into the immobile adult. This is why fishermen haul their boats from the sea during the month of May and scour and scrub their hulls, for the newly settled brood of barnacles is still easily removable, whereas in a week or two more they would form a firm encrustation. In the days of sailing ships the attachment and growth of vast numbers of barnacles, sessile and stalked, during a long voyage, materially obstructed the way of the ship.

Societies and Academies

LONDON

Geological Society, March 8. D. A. BRYN DAVIES: The Ordovician rocks of the Trefriw district, North Wales. The area described extends from Trefriw and Dolgarrog in the Conway valley south-westwards to Capel Curig. The Glanrafon beds are correlated with the beds immediately underlying the Snowdon volcanic suite in Snowdonia, and with the beds of the same name underlying the volcanic suite at Dolwyddelan. The Crafnant volcanic series is considered to represent an incomplete development of the Snowdonian suite, the bedded pyroclastic and probably also the upper rhyolitic series being absent. In the neighbourhood of Dolgarrog, the Crafnant series is faulted against a thick development of pumice-tuff and spilitic agglomerate overlain by rhyolite-tuff and rhyolite. These are regarded as contemporaneous with the Crafnant series, but representing, in part at least, the products of a different centre of activity. The fauna of the Llanrhychwyn Slates, comparing closely with that of the Lower Cadnant Shales of Conway, places the underlying volcanic series in the Llandeilian, and indicates its correlation with the upper part of the Conway Volcanic series. V. WILSON: The Corallian rocks of Yorkshire. (1) The Howardian Hills. Three divisions of the Corallian are recognised and their stratigraphical relations are dealt with in detail. The important rôle played by the spicular remains of the lithistid sponge *Rhaxella perforata* Hinde in the building up of the Lower Calcareous Grit is recognised for the first time. Calcareous, and many varieties of siliceous, spicules are described, and their distribution is discussed. Though perfect lithological continuity exists between the Lower Calcareous Grit and the overlying Osmington Oolite series, the absence of any representatives of the Hambleton Oolite series and the Middle Calcareous Grit containing fossils characteristic of these two divisions is considered to indicate the existence of a non-sequence in this area. In the later stages of the Osmington Oolite period reefs became established, and numerous facies deposits accumulated from the erosion of the reefs. As the Lower Calcareous Grit passes gradually into the Oxford Clay below, so the Upper Calcareous Grit gradually gives place to the overlying Kimeridge Clay in the North Grimston district, there being no unconformity such as was formerly supposed.

PARIS

Academy of Sciences, March 6 (*C.R.*, 196, 653–732). The President announced the death of Magnus de Sparre, *Correspondant* for the Section of Mechanics. E. MATHIAS: Contribution to the study of fulminating matter. The phases of its explosion by cooling. RENÉ LAGRANGE: Poncelet's theorem and a class of cyclids. GLAGOLEFF: Effective and general construction of the Cremona transformation in the plane and in space. JACQUES WINTER: An application of Schrödinger's theory of perturbations to a problem where the degenerescence persists up to the *n*th approximation (Mathieu's equation). HENRI CARTAN: Groups of pseudo-conformal transformations. N. ARONSZAJN: The decompositions of uniform functions. MLLE. ESTRADÈRE: The oxidation of some hydrocarbons. A study of the oxidation of hexane, cyclohexane and cyclohexene under conditions favourable to the production of explosions. M. KÉFÉLI: The suppression of rolling and pitching. J. DELSARTE: Spherical evolution. PIERRE VERNOTTI: The best method of assuring a thermal isolation. TH. V. IONESCU and MME. IRÈNE MIHUL: The absorption of energy in ionised gases. L. DUNOYER and P. PAOUNOFF: A state of working of photoelectric cells containing gas. G. RIBAUD: The measurement of the total factor of transmission of the coloured filters used in heterochrome photometry. A. HAUTOT: The structure of the *K* line of boron. This line has been described as having a width of 3 A. (Söderman) or 5 A. (Prins). With a spectrograph of high dispersion it has been found to be double, the two lines being 1·25 A. apart. PIERRE BRICOUT: A magnetic apparatus for the determination of thicknesses. The continuous and automatic measurement of the thickness of thin sheets or the diameter of fine wires is a problem of interest both in the laboratory and the works. The method described is applicable if the magnetic permeability of the specimen is practically equal to that of air: variations of 0·1 micron can be detected. K. BORATYNSKI and A. NOWAKOWSKI: The modifications of phosphoric anhydride. The crystalline modification has a specific gravity of 2·284 at 20° C., 2·207 being that of the amorphous modification. AUGUSTIN BOUTARIC and JEAN RATELADE: Rhythmic precipitation in stretched gels. A. PORTEVIN and P. BASTIEN: Contribution to the study of the physical and mechanical properties of the magnesium-aluminium-copper alloys, rich in magnesium. R. CAZAUD: The influence of the degree of cold hardening produced by wire drawing on the limit of fatigue of mild steel. GEORGES FOURNIER and MARCEL GUILLOT: The relation between the absorption of the β-rays by organic compounds and the molecular structure of the latter: halogen derivatives. PAUL BAUD: The soda factory of Nicolas Leblanc. A. TRAVERS and LU: The separation of phosphoric, arsenic and vanadic acids from aluminium. The vanadium is removed by heating to 400° C. in a current of gaseous hydrochloric acid. FÉLIX TROMBE: The preparation of metallic neodymium free from iron and silicon. The metal is prepared by electrolysis of the chloride, after removal of oxychloride by prolonged heating in dry hydrochloric acid. The metal is heated in a high vacuum at 1200° C. to remove potassium: it contains about 0·02 per cent of iron, less than 0·05 per cent of silicon and only spectrographic traces of calcium. R. TRUCHET: The oxidation of the true acetylenic hydrocarbons by selenious oxide. The preparation of α-acetylene alcohols. The oxidation of the hydrocarbon $CH_3.(CH_2)_4C{\equiv}CH$ with selenium dioxide gave the secondary alcohol $CH_3.(CH_2)_3.CH(OH).C{\equiv}CH$. The next homologue, octyne, behaved in a similar manner on oxidation. L. Royer: The orientation of certain crystals by hydrargillite. A peculiarity in the orientation of crystals deposited in contact with macled calcite. L. J. Spencer: The origin of tectites. Michel and Lacroix have suggested that tectites are formed in the atmosphere from meteoric materials composed of silicon and the light metals, fused by the heat developed by friction with the air. The author suggests an alternative hypothesis according to which meteorites of meteoric iron impinging on desert sand have developed sufficient heat to melt the sand into a silica glass. This accords with the high percentage of silica found in tectites (see also Nature, 131, 117, Jan. 28, 1933). F. Blondel: The average amount extracted from copper minerals. A. Marin and P. Fallot: The connexion of the dislocations of Punta Piscadores with those of the limestone chain of the Rif. C. E. Brazier and L. Génaux: Some remarks concerning the earthquake of March 2, 1933. Discussion of the results obtained on the seismograms at the Observatory at Parc Saint-Maur. Ch. Maurain: Remarks on the preceding communication. The amplitudes of the movements of the ground recorded during the earthquake of March 2 last are probably the greatest ever observed in the Paris region for movements of seismic origin. Henry Hubert: The climates of the French tropical domain. Zb. Sujkowski: The presence of Radiolaria of the Phæodaria group in the lower Carboniferous of Poland. René Vandendries and Harold J. Brodie: The sexual radiations in the Fungi. Mlle. M. L. Verrier: The eyes and vision of *Cerastes vipera* and *Vipera aspis*. Mme. Andrée Drilhon: Phosphorus and moulting in crustaceans. Mme. Hufnagel and Marcel Joly: The action of the X-rays on the metamorphosis of insects. Robert Sorel: Tincture of iodine and asepsis. The author questions the utility of tincture of iodine used as a preliminary wash for the skin in surgical operations, especially if lengthy. It appears to act as a varnish, and results as good can be obtained with a varnish not containing an antiseptic.

Forthcoming Events

Monday, April 24

University of Cambridge, at 12—(Rouse Ball Foundation Lecture).—Prof. B. L. Van der Waerden: "The Aims of Modern Algebra".

Royal Geographical Society, at 5.30—(Film).—R. J. Flaherty: "South Pacific Pictures".

National Institute of Industrial Psychology, at 6—(at the London School of Economics, Houghton Street, W.C.2).—Mrs. W. Raphael: "The Selection and Training of Office Staff".

Royal Society of Arts, at 8—(Cantor Lectures).—W. Augustus Steward: "Goldsmiths' and Silversmiths' Work—Past and Present" (succeeding lectures on May 1 and 8).

Tuesday, April 25

Eugenics Society, at 5.30—(at the Rooms of the Royal Society, Burlington House, Piccadilly, W.1).—Symposium on "Eugenics and Religion". Speakers: Capt. G. H. L. F. Pitt-Rivers and the Rev. A. H. Gray.

Gresham Lectures in Astronomy, at 6—(at Gresham College, Basinghall Street, E.C.2).—A. R. Hinks: "The Star Map of the Future" (succeeding lectures on April 26, 27 and 28).

Institution of Civil Engineers, at 6.—H. G. E. Cherry: "The Influence of Earthquakes on Structural Design". F. W. Furkert: "The Effect of Earthquakes on Engineering Structures". J. J. Booth: "The Design of an Earthquake-Resisting Structure: The Dominion Museum, Wellington, New Zealand".

Wednesday, April 26

London School of Economics, at 5.—Prof. A. W. Marget: "The Natural Rate of Interest" (succeeding lectures on April 27 and May 3 and 4).

Royal Society of Arts, at 8.—Dr. W. H. Gibson: "Future Developments in the Flax and Linen Industries".

Thursday, April 27

London Mathematical Society, at 5—(at Burlington House, Piccadilly, W.1).—Prof. B. L. van der Waerden: "Hypercomplex Numbers".

Institution of Electrical Engineers, at 6—(Twenty-fourth Kelvin Lecture).—Sir Frank E. Smith: "The Travel of Wireless Waves".

Friday, April 28

Association of Economic Biologists, at 11.45—(in the Botany Lecture Theatre, Imperial College of Science and Technology).—Dr. S. Dickinson: "The Nature of Saltation in *Fusarium fructigenum*". At 2.30, Special General Meeting. At 2.45, Dr. C. B. Williams: "Observations on the Desert Locust in East Africa"; A. M. Massee: "The Strawberry Tarsonemid Mite".

Society of Chemical Industry (Chemical Engineering Group), at 6.45—(at the Waldorf Hotel, Aldwych, London, W.C.2).—Annual General Meeting. The Right Hon. Lord Melchett: "Modern Economics and Unemployment".

Royal Institution, at 9.—Dr. James Gray: "The Muscular Movements of Fishes".

Faraday Society, April 24–25—(at the Royal Institution, Albemarle Street, London, W.1).—General Discussion: "Liquid Crystals and Anisotropic Melts".

Biotechnology

IN an address to the University of New Zealand, referred to briefly in NATURE of April 15, p. 538, the Chancellor, Dr. J. Macmillan Brown, emphasised the need for building university education on broader foundations than the narrow specialisation which seems to prevail. Every degree, however specialised or technical, should have as its first stage the broadest culture possible. In this Dr. Macmillan Brown was only echoing a point of view stressed at greater length by Dr. Flexner in his well-known work "Universities: English, American and German", as well as by Prof. Findlay and others in recent addresses. The absence of anything like a true *universitas literarum* has long been lamented by close observers of our university life who have seen the dangers of the rapid development and inevitable specialisation, which result in young men of all countries being so immersed in their own special branches of science that they have scarcely the time or energy to devote to the study of more comprehensive problems.

The peril is indeed increasing, and the tendency to over-specialisation, to exclusive preoccupation with one small field of science, is definitely greater than a couple of decades ago. Even industry is suffering from the absence of perspective in the recruits which it now draws from the universities, and this the more in that, as the general cultural level falls, the demand for a sense of values and of perspective increases, industrial advance like scientific development originating more and more in the borderline sciences which are common ground to two or more of the great divisions of knowledge. Science is, after all, only one of the many civilised activities of mankind and inevitably suffers from any prolonged isolation from those other activities. The specialists' knowledge must therefore be supplemented by comprehensive surveys of the problems before science.

The value of such contributions, not merely to the understanding of the present position of science but also to the interpretation of the many difficult social, economic, and political problems with which our civilisation is confronted, is scarcely to be computed by those who have received no training in science. The need to-day is for those who can truly interpret the values of human life, and recent literature testifies not merely to the capacity of the man of science to assess such values, but also to the indisputable fact that when he is freed by a broad culture and outlook from the restraints of a narrow specialisation, he forms such judgments of value like all other men, and that indeed to become an investigator demands a certain sense for judgments of value. Moreover, even in specialisation at its worst, the man of science has learnt to discard the dogmatism with which he so justly reproached the theologian of a former generation, but with which he was frequently strongly tainted himself.

The change which has come over science in this respect can scarcely be attributed to the tendency of scientific laws, even in modern chemistry and physics, to assume the character of average or statistical laws, or even to the convergence of scientific investigation. It may be due in part to the realisation that the classification of the sciences is largely arbitrary and inadequate—that differences existing between physics and history or biology, for example, are mainly in the complexity of the material and not in the method. Human actions in history are so overwhelmingly complicated that general laws are much more difficult to discover, and consequently to apply, than are physico-chemical laws. It may be due, further, to the recognition that it is fundamentally wrong to believe that we now hold in our hands the absolute and final truth in any category value. As Einstein has said, every scientific theory can be, and needs to be, merged in a higher and more comprehensive theory from which it finally receives its limits.

On the other hand, if the limitations of science are now more clearly perceived, it is also true that the tacit assumption behind the whole of scientific knowledge—that knowledge is possible concerning an objective set of facts, in other words, that there is such a thing as truth—has become more and more unassailable. We are indeed leading up to a final condition of physics in which all past discoveries are comprehended in a single unitary logical structure which is independent of the various possible methods of approach.

An outstanding feature of the present position is that we are now able to state very exactly where lie the problems still to be solved, and the chances of a really fundamental new discovery by random experiment or purely speculative theorising are well-nigh negligible. All really great theoretical and experimental discoveries of the last decade have been made by trained specialists, and in the main by men who had long reached the highest eminence in science. This position does not indeed entitle us to believe that investigation in this field is likely to become stagnant. It may, on the contrary, begin deductively in greater earnest. It does, however, provide some real explanation of the strong plea for the concentration of effort on the human sciences, where the greater complexities have delayed advance to a comparable extent and where the true laws have largely to be discovered.

To grant this is not to concede that the sole object of science is to understand the present state of affairs ; its goal is rather the whole course of events in the past, present and future. What is clear to even the most casual observer is that man's development has been unbalanced. His knowledge of physical laws and his control over physical forces is out of all proportion to his knowledge of biology or of the sciences concerned with man, still more with the growth of ethics and morality. For example, it is well known that there are inherited differences in cultural endowment among the members of a people, and these endowments are on an average proportional to the social level of the various layers. It is equally well known that in all modern civilised nations the relative increase in population is inversely proportional to the social level. The corollary that the civilised European nations are allowing their leading cultural elements to die out is, however, not generally faced. Few grasp the extent to which our modern social, hygienic and educational measures promote the well-being of the individual at the cost of humanity. The future of the world lies with the race that is the first to apprehend the true causes of cultural decay and to resolve to eliminate these causes.

At this point we touch an ideal characteristic of our modern Western civilisation—the technical ideal of fitness for a purpose for its own sake. This ideal, as distinct from mere utility, is behind much of the opinion urging the rationalisation of industry, the movement for scientific management, for scientific administration. It is in the direct succession of the ideal of pure science, the discovery of truth for truth's sake—a late conception in the development of humanity. In the technical ideal the fact that elimination of waste of material or effort, for example, in bridge building, involves a saving in cost is purely secondary if not irrelevant. Construction to fulfil the technical ideal must achieve the best possible result with the least possible means. To state, therefore, that technology demands the fulfilment of a purpose by the most suitable means and that quite commonly it consists in the choice of the correct means to achieve that given end, is to realise the immense significance of technology for every side of our social life to-day and the value of liberating it from a mere pecuniary conception of the principle of economy.

It is incontestable that, even in this narrow sense, technical progress has been of immense economic advantage to the world and has raised the average standard of living very considerably. Moreover, the regrettable results of industrialisation and the mechanisation of industry are less the direct responsibility of technology than of economic developments connected with particular technical achievements. None the less, profound problems are raised at this stage. It is possible that wise statesmanship may yet avert the worst consequences of such economic developments by foresight and appropriate action. In particular, there is the problem of leisure and how far it can be utilised to balance the mechanising influence of work and those other influences which perpetuate or increase the ratio of undesirable work.

The whole effect of technology upon our spiritual and mental life has yet to be examined. Once we accept the facts that the advance of science, both pure and applied, and the command of man over Nature cannot be resisted, we are compelled to face the problem how such developments can be made to conform to the elementary spiritual needs of mankind, which themselves cannot be abolished by simple decree.

Aeroplane and Camera in Anthropological Fieldwork

Äthiopen des Westens : Forschungsreisen in Portugiesisch-Guinea. Von Hugo Adolf Bernatzik. Mit einem Beitrag von Bernhard Struck. Band 1. Pp. xii + 303 + 12 plates. Band 2. 152 plates. (Wien : L. W. Seidel und Sohn, 1933.) 135 gold marks.

TO state that "Äthiopen des Westens" is a sumptuous production is not to exaggerate the lavish feast which this beautifully produced work unfolds to the eye. To write that the 531 plates—400 of which form the sole contents of vol. 2—comprise the *pièce de résistance*, is not to belittle the narrative matter which constitutes the greater part of the text of vol. 1.

Dr. Bernatzik has summoned the camera and the aeroplane to be his interpreters in his successful attempt to portray the life of the inhabitants of little-known Portuguese Guinea. The result is, very literally, a vivid series of pictures of the peoples among whom he travelled. Prof. Struck's contribution supplies—what may have been deemed the necessary—more strictly scientific touch. It deserves special notice which it will presently receive.

This must surely be the first occasion—if we omit Lady Bailey's survey flights in North Africa, and the solo flight over the Gold Coast of a professional anthropologist in 1929—upon which the aeroplane has been called in to assist the anthropological field-worker. Perhaps only those who know the ever present and dread possibilities of forced landings when flying over tropical forests, can fully appreciate the skill and courage of the airwoman, Fraulein Elli Beinhorn, which made possible the many bird's-eye views of native houses and homesteads. Dr. Bernatzik's methods were, throughout, simple and straightforward. Handicapped by a lack of knowledge of the local vernaculars, he was compelled to rely more on what he could himself observe than on what he heard or was told. He has taken each of some dozen tribes in turn, and under such headings as religion, birth, marriage, funeral rites, dances, law, love-making, etc., has described what any trained and careful observer would be likely to see with his own eyes. He has then recorded these sights and scenes with the aid of an artistic wife and of a fine camera. The rites and customs which he describes exhibit many of the features which we are now beginning to find common to most West African primitive societies, the more we come to know about such communities. Ideas on land tenure ; law ; standards of morality, where the desire for children far outweighs any narrow jealous feeling of sexual prerogative on the part of a childless spouse ; the absence of chiefs—in the narrower territorial sense—all these and many other customs described are found among other west coast peoples.

One statement, however, made by Dr. Bernatzik seems so extraordinary as to merit some doubt as to whether he has not either been misinformed or misled. He writes, speaking of the Balante, that they do not believe in a life after death ; that they do not follow the cult of ancestor worship, that they do not fear the dead. All this, too, in West Africa, where the cult of ancestors is the keystone of all religious beliefs. It seems well-nigh impossible.

The reviewer was struck with the old priest's description of a great tree which had withstood a forest fire for twenty days, standing up when all around it had been destroyed, "a mighty glowing column", thus justifying and augmenting its previous claim to divinity. The story recalled vividly a similar spectacle which the writer once saw in West Africa. Wandering in the forest one misty morning, he saw through the harmattan haze an immense column of incandescent radiance, towering some 250 feet into the sky. The sight was so wonderful and uncanny as at first to inspire a feeling akin to awe. This strange phenomenon proved, however, on closer inspection to be only a gigantic tree, which from base to summit was a white-hot mass of glowing charcoal. It emitted neither smoke nor sparks but shimmered with a white heat. After witnessing such a sight, it is not difficult to understand how a blackened tree stump may have become a pagan god.

Reference has already been made to Prof. B. Struck's contribution to this work. His chapter on physical measurements may be said to supply the more strictly scientific background for Dr. Bernatzik's more simple narrative and wonderful pictorial setting. The social anthropologist has here asked the physical anthropological expert to come to his aid in order to do full justice to this important part of the work under review. Dr. L. H. Dudley Buxton writes as follows:

"Prof. Struck's contribution to the physical anthropology of this region, which is little known, is a very important one. The author gives a careful reference to the methods used—a precision unfortunately only too rare. He always prints the numbers of the definitions given in Martin's 'Lehrbuch'; in particular, he directs attention to the question of the position of the nasion, in which case Martin's method is adopted, it would appear, with some reluctance. On this very important point, for the nasal index is extremely significant in many parts of the west coast, the author seems satisfied on internal evidence, namely, the comparison between the various groups, that he was working consistently with others in the field. To the critic who is constantly faced with the doubt as to whether the work of different observers is comparable, Prof. Struck's paper is for all these reasons extremely welcome.

"There are, however, some points to which criticism may be fairly directed. No one knows better than the field-worker how very difficult it is to get adequate numbers of subjects, and in most cases the author's groups are sufficiently large for satisfactory comparison. On the other hand, it would be a hazardous undertaking to base any conclusions on the comparison of groups which contain only a few individuals; it would perhaps have been safer with our present knowledge, either simply to publish the means of the smaller groups without drawing any deductions, or, where it is possible, to use the method followed in the case of the Balante and Pepel and to pool the subgroups, where there is reason to believe that such a pooling is justifiable. Next, it would seem inadequate merely to publish means; the constants of variation and probable errors should certainly be added, especially where comparisons between individual measurements are made. The author's method is to consider each measurement individually, and to compare the various tribes.

"Much as one might have wished for a general summary, obviously the material was inadequate for this and the restraint of which this absence is evidence is not the least commendable part of a paper which should be of very great value to all students of the physical types of West Africa."

R. S. R.

The Trinkler Expedition to Central Asia

Geographische Forschungen im westlichen Zentralasien und Karakorum-Himalaya. Von Dr. Emil Trinkler. (Wissenschaftliche Ergebnisse der Dr. Trinkler'schen Zentralasien-Expedition, bearbeitet von Dr. E. Trinkler und Dr. H. de Terra, Band 1.) Pp. viii+134+16 plates. (Berlin: Dietrich Reimer (Ernst Vohsen) A.-G., 1932.) 32 gold marks.

Geologische Forschungen im westlichen K'unlun und Karakorum-Himalaya. Von Dr. Hellmut de Terra. Mit Beiträgen von G. Fischer, W. Gothan, P. Vinassa de Regny, O. H. Schindewolf, J. Schuster, K. Staesche. (Wissenschaftliche Ergebnisse der Dr. Trinkler'schen Zentralasien-Expedition, Band 2.) Pp. x+196+22 plates. (Berlin: Dietrich Reimer (Ernst Vohsen) A.-G., 1932.) 44 gold marks.

THE name of Dr. Emil Trinkler must be added to the growing list of those who, having risked health and life itself in the cause of science in distant lands, have fallen victims to the perils of modern civilisation. T. Alexander Barns, after years of exploration in Central Africa, was killed in a motor accident in Chicago; Dr.

Trinkler, after such narrow escapes from disaster in the uninhabited Kunlun as when all but one of his yaks perished, also died as the result of a motor accident—in Bremerhaven in April 1931. He was but a young man of thirty-five years when he died but he has left behind a record of solid work which will remain as an important contribution to the elucidation of the structural and morphological history of the Karakoram, Kunlun and Taklamakan regions.

Dr. Trinkler first became prominent as having made a lengthy tour through Afghanistan in 1923. He showed himself a man of resource in travel and of sound ability in the marshalling of facts and sifting of evidence collected by his predecessors. As a result his "Afghanistan, eine landeskundliche Studie" (J. Perthes, Gotha, 1928) is a standard work on the country. His second and more ambitious journey, undertaken in 1927–28, was preceded by a careful study of the work of previous explorers in the Eastern Karakoram, and so he was able to select a region that had been comparatively neglected. From Leh in Kashmir he followed an eastern route across the western end of the Tibetan plateau to the Kara-Kash River; over the Kunlun to the Taklamakan depression. After considerable journeys there he returned to Leh by the better-known route of the Karakoram Pass. By choosing this circular route the geological results include a complete double traverse of the Karakoram and Kunlun chains, whilst the leader was able to make a special study of one of the problems he regarded as of special interest—the history of glaciation in this region.

Dr. Trinkler wrote a popular account of his journey, "Im Land der Stürme" (F. A. Brockhaus, Leipzig, 1930) and a number of technical papers. The latter include two in English—his conclusions relative to the Ice Age (*Geog. J.*, 75, 225–232; 1930) and a general account of his journey (*Ibid.*, 75, 505–517; 1930). His detailed account of the geographical observations was almost ready for press at the time of his death and so has appeared posthumously, edited by Frau Ilse Trinkler and G. Köhler. For this thanks are also due to Dr. H. de Terra, the geologist of the party, who was a fellow student of Trinkler's at Munich and is now research associate in geology at Yale. Simultaneously, Dr. de Terra has published his geological observations; the archæological results of the expedition, which are being worked out in the Bremen Museum, have still to appear.

(1) The geographical volume is divided into two parts. The first deals with the mountain belt between the Upper Indus valley at Leh and the Tarim Basin; the second with the western part of the Tarim Basin itself. In the first part the features observed on each stage of the journey are described in sequence with the help of sketches and photographs. A number of the latter are by W. Bosshard, a Swiss, who formed the third European member of the expedition. Special attention is given to morphology and a contrast drawn between the accidented topography of the Tertiary ranges and the round outlines of the hills which rise from the surface of the Tibetan plateau.

It is a legitimate presumption that when the great Ice Age covered the whole of Northern Europe and the northern parts of Northern America with ice sheets, Central Asia should also have been the seat of a huge ice-sheet. A review of the evidence leaves no doubt that the glaciers of the Kunlun, Karakoram and Himalayas were formerly much more extensive. Dainelli, who accompanied the Italian expedition led by De Filippi in 1913–14, found evidence in the Karakoram for four great glacial periods corresponding with the Mindel, Riss, Würm and Post-Würm stages in the Alps. Although the moraines of the first two glaciations are poorly preserved, Trinkler does not appear to doubt this interpretation. He considers that during the later glacial periods the snow line was 2,000–3,000 ft. lower than at present and that glaciers descended in the Kunlun to 8,000 ft. or 9,000 ft. above sea-level. It may even be that Dainelli is right in believing that the big Indus glacier ended with its snout in the lake which formerly occupied the Attock plateau of the Punjab at less than 2,000 ft.

Whether the great Tibetan plateau, the roof of the world, was covered by a huge ice-sheet is, however, another matter. The temperature was, of course, low enough, but did not the southern ranges—the Himalayas—intercept the moisture-laden winds just as they do to-day and prevent sufficient precipitation? Trinkler admits that striated boulders and polished rocks are extremely rare, but points out that disintegration of exposed rocks is very rapid owing to the strong insolation. Further, typical V-shaped valleys are absent on the plateau. Trinkler therefore comes to the same conclusion as Prinz did in the Pamirs, that the broad valley-plains of the Tibetan plateau were more or less filled with *stagnant Tafeleis* (Highland ice) which left little trace on melting. Only on the margins where movement was possible did it carry out the work of erosion characteristically associated with ice-sheets. In connexion with precipitation on the plateau, it is interesting to note that Trinkler asserts positively that the Indian monsoon penetrates far into the interior, though winter snowfall is also brought by depressions from the west.

(2) Dr. de Terra has secured the collaboration of a number of experts in preparing his volume on the geological results of the expedition. He gives a brief introductory outline enumerating the orographic units and then proceeds to a detailed account of his observations. Especially valuable are the numerous sketches and simplified block diagrams illustrating the relationships between structure and topography. A coloured map on the scale of 1 : 1,000,000 is included and on p. 112 the author attempts two generalised sections from Leh to the Kunlun. Three distinct belts stand out clearly : (1) the highly folded Himalayan-Mustagh or Karakoram belt in which gneisses, schists, metamorphosed older Palæozoics and intrusive granites predominate ; (2) the highly folded Kunlun belt where again gneisses and granites play a very large part ; and (3) the intervening belt of plateaux in which gently folded Triassic limestones predominate but where younger Palæozoic (Carboniferous-Permian) as well as Cretaceous rocks are also present. The last belt formed part of the Tethsy until late Cretaceous times.

There is, of course, an important distinction between the Himalayan fold-belt in which Tertiary rocks are involved and the Kunlun fold-belt, folded and uplifted in Permian times. The old Kunlun system, Dr. de Terra discovered, is separated from the geologically younger folded regions of the Tibetan plateau by a belt of faulting which is marked by a broad plain-like valley running along the southern foot of the main Kunlun range. In general, both in the Kunlun and Karakoram, tectonic and orographic strikes correspond.

The latter part of de Terra's volume is occupied by a description of hand specimens and fossils. Both Dr. Trinkler and Dr. de Terra have much of interest to add to what is already known of the Taklamakan, but their contribution to the knowledge of the mountain wall which separates India from Chinese Turkestan is of outstanding importance.

L. Dudley Stamp.

Hydro- and Aerodynamics

Handbuch der Experimentalphysik. Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 4: *Hydro- und Aerodynamik.* Teil 4: *Rohre, Offene Gerinne, Zähigkeit.* Herausgegeben von Ludwig Schiller. Bearbeitet von L. Schiller, F. Eisner, S. Erk. Pp. viii + 719. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932.) 67 gold marks.

THIS fourth and concluding volume of the part of the "Handbuch der Experimentalphysik" devoted to the subject of hydro- and aerodynamics fully maintains the high standard set by the three preceding volumes. It comprises three long articles dealing respectively with the flow in pipes, the flow in open channels and the measurement of viscosity, and it also contains a useful general index to the whole four volumes.

The first article, by Prof. L. Schiller, is noteworthy for its critical discussion of the subject and for its clear exposition of both the theoretical and experimental investigation of the flow in pipes. The work of Schiller himself and that conducted under his direction at Leipzig have contributed greatly to our knowledge of this subject and in particular to a proper understanding of the influence of different entry conditions and their effect on the pressure loss along a pipe. After a clear exposition of the principles of dynamical similarity and of the precautions necessary in the measurement of velocity and pressure, Schiller discusses in turn the laminar and turbulent flow in circular pipes and transition from one type to the other. An excellent and valuable summary of the best experimental results is supplemented by a discussion of the latest theoretical developments, in which turbulent flow is analysed on the basis of Prandtl's conception of a *Mischungsweg*. The article concludes with relatively brief discussions of the flow in non-circular, divergent, curved and rough pipes.

The flow in open channels is discussed by Dr. F. Eisner in the second article. This subject is far more complex than the flow in pipes owing to the presence of the free surface, the conditions for full dynamical similarity are more complex and indeed prevent any exact model experiments, and the problems tend to assume a practical engineering rather than a scientific aspect. After a rather tedious discussion of the conditions of dynamical similarity, Eisner gives a valuable account of the experimental technique and apparatus with special attention to the determination of the form of the free surface. This is supplemented in a later section by descriptions of the ingenious devices used for creating tides and waves. The major part of Eisner's article is, however, devoted to a detailed description of experimental results covering a wide range of subjects, and particular mention may be made of his excellent account of wave motion.

The third article, by Dr. S. Erk, deals with the measurement of viscosity. Numerous types of viscometer, suitable for different fluids and different experimental conditions, are fully described, and the experimental results for a large variety of gases and liquids are then tabulated and discussed in the light of existing theories. The article concludes with a brief account of the methods of measuring the viscosity of solid bodies. The treatment of the subject is throughout clear and comprehensive, but there are unfortunately several incorrect references to tables and figures.

A Treatise on Coordinate Geometry

Elements of Coordinate Geometry. By J. M. Child. Pp. xiii + 468. (London: Macmillan and Co., Ltd., 1933.) 12*s*. 6*d*. net.

THE outstanding feature of this substantial treatise on coordinate geometry of two dimensions is the full and elaborate account which it gives of the theory of the subject. In consequence, the volume should prove a useful manual for students preparing for scholarship and honours degree examinations.

The first chapter contains a discussion of the representation of real numbers by points on a directed line; and this, naturally, raises the problem of the irrational number, which Mr. Child defines by means of sequences of rational numbers. Curiously enough, he does not point out that the number so defined may be rational. It must be confessed that his phraseology in dealing with limits is somewhat loose.

Before introducing the equation of the straight line, Mr. Child devotes a chapter to the plotting of statistics. He defines the positive direction of the straight line as that in which x increases. It is doubtful if anything is gained in coordinate geometry by giving direction to the straight line. The direction makes no difference to the gradient formula, on which the theory of the straight line can most simply be based.

Useful features of the book are the very full discussions of the general equation of the second degree and the sections on polar coordinates. The treatment of tangents, based on the theory of monotonic sequences, is interesting, though it scarcely seems necessary to bring in the idea of 'time'.

Later chapters deal with conics, cross-ratios, the "line at infinity" and homogeneous coordinates. The book is intended to stress the advantage of coordinate geometry as "a powerful analytical weapon of attack" and consequently the pure geometry of conics is only dealt with incidentally. Here and there interesting historical notes are given, and there are plentiful collections of examples, of varied difficulty, with answers supplied.

T. M. M.

Short Reviews

The Life Histories of New Zealand Birds. By Edgar F. Stead. Pp. xvi + 162 + 93 plates. (London: The Search Publishing Co., Ltd., 1932.) 30*s*. net.

IN this book we have Mr. Edgar F. Stead doing for New Zealand birds what Mr. Arthur C. Bent is doing for American birds. Each is an expert and the result is a great gain to knowledge.

In New Zealand we find the evil of man's introduction of the stoats and weasels. The birds, which never before had this enemy, now find life made hard for them. Amongst the waders we find a detailed account of the double-banded dotterel, so common in New Zealand and Australia, but breeding only in the former country. Its migration, north to Norfolk and Lord Howe Islands then to the east coast of Australia and so on to south-west Australia, is one of the extraordinary movements amongst birds.

We find now that the black fan-tail is only a variant of the pied one; mated birds produce the pure black bird and in the same nest, pied birds, as many workers have contended.

Under the shags we find the old superstition that these birds are the fisherman's enemy and destroy fish that he should catch. New Zealand has many shags, most of them very common indeed, yet more fish are caught each year than in the previous one. The skua, with its bad reputation, here as elsewhere, is given an autobiography in spite of its depredations on the delightful mottled petrel.

The splendid plates add greatly to the charm of the book, and the author's pleasant style of writing will attract the reader, who will be interested and instructed while reading the book. It will be a useful and necessary companion to Oliver's book "New Zealand Birds" which we reviewed last year. At the end of the book is a description of the eggs of the eighteen species of which the life histories have been described.

Handbuch der Vererbungswissenschaft. Herausgegeben von E. Baur und M. Hartmann. Lief. 15 (Bd. 3, L): *Entstehung der Kulturpflanzen.* Von E. Schiemann. Pp. ix + 377. (Berlin: Gebrüder Borntraeger, 1932.) 50 gold marks.

This textbook endeavours to present a comprehensive review of the origin of cultivated plants, considered from the historical and biological points of view. The preliminary general discussion deals with our historical knowledge of the various crops, after which comparative morphology, geographical distribution and genetics are considered in their relation to crop plants. The range of the inquiry is wide, embracing in addition morphology, physiology and problems of variability. Where a crop plant occurs in both wild and cultivated forms, it is pointed out that its origin is usually to be sought where the wild type occurs.

Individual crops receive separate treatment, most of the common agricultural plants such as cereals, potatoes, Leguminosæ, etc., and a few of the more important horticultural crops as tomatoes, fruit, grapes, etc., being discussed in detail. A full bibliography of some twelve hundred titles, and tables giving a general summary of the main results, round up a most useful work of reference.

The Gestalt Theory and the Problem of Configuration. By Bruno Petermann. Translated by Meyer Fortes. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xi + 344. (London: Kegan Paul and Co., Ltd., 1932.) 15*s.* net.

Among the psychological theories, the doctrine of *Gestalt* or 'configurationism' has won general attention only recently, though it grew contemporaneously with behaviourism. Its importance, however, is none the less very great in so far as it furnishes an alternative approach to the psycho-physiological problem of human and animal behaviour. The general conception of 'configurationism' is to stress organised wholes as they occur in experience and in performance rather than their elements, as does the older psychology. This method makes possible an alternative treatment of behaviour, of perception and even of learning, though the results obtained in this respect are not yet final. The particular value of the book under review is that it not only explains the aims, method and results of the *Gestalt* theory, but that it also makes a searching criticism of this doctrine, indicating at the same time the conditions for its future progress.

T. G.

Organic Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Frank C. Whitmore, Editor-in-Chief. Vol. 12. Pp. vii + 96. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 10*s.* 6*d.* net.

The latest volume of this series contains details of the preparation of thirty useful substances. Among them are *p*-chlorobenzaldehyde, *p*-tolualdehyde, desyl chloride, succinic anhydride, mercury di-β-naphthyl, and diethyl zinc. The preparation of 2,4-dinitrobenzaldehyde (a reagent of value for characterising amines and substances with a reactive methylene group) is a particularly interesting process, depending upon the reaction between *p*-nitrosodimethylaniline and 2,4-dinitrotoluene, whereby the methyl group of the latter substance is eventually transformed into an aldehyde group, leaving *p*-aminodimethylaniline as a by-product.

This issue is the third volume not embraced in the recent collective work, and it is therefore useful that the index to vol. 12 has been extended to cover the contents of vols. 10 and 11 also.

J. R.

L'Année psychologique. Publiée par Prof. Henri Piéron. Année 32 (1931). Vol. 1. Pp. xx + 480. Vol. 2. Pp. 481–949. (Paris: Félix Alcan, 1932.) 120 francs.

As usual, this yearly publication contains some very important original essays and a mass of reviews (1,670 in number) of the current literature of psychology. It will suffice to mention some of the subjects treated: chromatic sensation (Piéron), mental work without movements (Foucault), nervous rhythms and relaxation oscillations (Fessard), complexity of consecutive visual impressions (Durey), appreciation of time in the white mouse (Ruch). At the end of this work there is an appeal by Prof. Spearman, to the effect that psychologists should agree once for all about the conditions and interpretations of certain experiments, on the lines followed by physicists.

A French-English Vocabulary in Geology and Physical Geography. By G. M. Davies. Pp. ix + 140. (London: Thomas Murby and Co.; New York: D. Van Nostrand Co., 1932.) 6*s.* net.

This vocabulary contains between four and five thousand words. Most of them are either technical terms or words in common use which have special technical or colloquial meanings. The inclusion of the English equivalents of a number of unfamiliar place names adds to the usefulness of the vocabulary. An appendix contains a comparative table of English and Continental stratigraphical terms. The lack of such a glossary as this, devoted especially to geology and its allied sciences, has long been apparent. It should prove invaluable to many English readers of French works on geology and geography.

Agriculture and Milk Supply[*]

By PROF. HENRY E. ARMSTRONG, F.R.S.

"Nought shall make us rue
If England to itself do rest but true."

WE take our time in minding the Bastard's advice—concerning ourselves more with Far Eastern questions than with our own, even with such minor, polar moments as hard hitting above the cricket belt and dog totes. In fact, our one popular use of our land is playing games upon it: also as gladiators but upon rubber tyres and oil-fouling our tracks as we go, mercilessly and without turning down of thumbs running each other down, under sanction of third party insurance! Those who set themselves over us, by right of caucus, have long ceased to think of the land in constructive, sympathetic terms or otherwise than as affording opportunity for the *greatest of all games—taxation!* Agricultural research is become an underground business, with little interest in sun-bathing; dealing with bacteria mostly—a form of life to which, ultimately, we must all succumb. In Egyptian times, some care was taken of our bodies—to-day we are simply handing them over to commercial exploitation: to universal undertakers called canners. We calmly cut our food not from the joint with two vegetables but out of sealed 'coffins'. Fresh food will soon be unseen and unsold! Health must steadily deteriorate. We call the game we are fatuously playing—Progress; perchance, the name will ere long perforce be changed to Perdition. Well may we ask with Bunthorne:

"Is it and can it be
Nature hath this decree
Nothing poetic in the world shall dwell?"

Nothing natural? Is our agriculture coming to an end?

The issue I would raise is—*Are we to use our land to produce fresh whole food—to make ourselves a whole people, our animals whole stock?* Alternatively, are we to allow tubercular disease, cancer, appendicitis, foot and mouth—deficiency diseases generally—to ravage our population? Malnutrition to prevail everywhere? Is our land to be highly fed and used up to the hilt of production and employment or is it to go derelict—to favour machinery and commercial lust? Many industrialists would calmly put the countryman aside—just use him to keep the hedges trim; so that they may sell their wares abroad, they would allow unconditional free entry to other people's farm products without reference to quality. Such form of civil war is even looked upon as a means of cementing family ties: it was at Ottawa. In the sacred name of Imperial Preference, we are to allow our wheat to be grown in Canada and Australia, our milk to be made in New Zealand! Our eggs and butter also at the Antipodes. As to meat, we help in every way its introduction into our markets, in merciless competition with that raised upon our own soil: under the ægis of the Department of Scientific and Industrial Research, public funds are lavishly spent on the study of the means of preserving it and other food, so that they may be brought to us from long distances. Home produced food materials receive little scientific attention.

The fault lies with our own fraternity of science, in that we have in every way aided commercial, industrial development, without considering the ultimate effect upon the general welfare. No proper social use has been made of knowledge—the national education has been and still is in the hands of people who have no eyes to see and but play with words: the Head of Eton becomes Dean of Durham. We are still under monastic rule.

"New times demand new manners and new men." The cry was uttered long ago by an American advocate of freedom. The men who would lead the world to-day are old and without any manners that are new: they have no regard for the method of discovery—the one gift the world has received in modern times; unfortunately, by unrighteous and partial use the gift has brought the world to its present intolerable position.

A decision must soon be taken—what proportional share and part agriculture is to have in our social economy. That we must play the game with our land cannot be denied. It is the only ultimate asset we shall have, as an island people, if and when all else fail us. To maintain a fit and happy race, we must needs preserve a rural population. Prices must be established at such agreed levels that we can make most use of men and least use of machines. It cannot be that we shall sink so low, through commercial avarice and worship of the unholy doctrine of always buying in the cheapest market, that we shall decline to use to the full the great God-given machine that we have in the sun. Chemistry forbids: the forgotten law of the conservation of energy. Manufacturing industry is but dissipation of energy, when carried on with coal.

To-day, the chemist can have but one opinion, if he consider the needs of the world. This is, that the first use we make of our science—of scientific method—should be on behalf of our food supply, in farming. Thus far, the farm has been considered from the point of view of a far too narrow economics—commercially and statistically, in terms of output. So great, however, has been our progress in the scientific study of food problems, especially during the past twenty years, that we are now able to envisage the place and object of agriculture from an entirely new angle: *that of nutritive value.* We know that malnutrition prevails the world over.

The future fulcrum of our agriculture must undoubtedly be milk—the food of foods, the food of infancy, the one and only complete food known to man. America is far ahead of Great Britain in its appreciation and use of milk. Here, the medical profession has never properly encouraged its use —being so deadly afraid of the organism provocative of tubercular disease. There has been no public opinion on the subject and too little attention has been paid to quality: although, of late, there has been a marked improvement, none the less, the average quality is far too low.

---

[*] Ministry of Agriculture and Fisheries. Report of the Reorganisation Committee for Milk. (Economic Series, No. 38.) Pp. 228+xx. (London: H.M. Stationery Office, 1933.) 6*d*. net.

So far are we from being alive to the need of using scientific method and knowledge in the service of the State, that only laymen were appointed by the Ministry of Agriculture, as members of the special commission the Report of which on the Reorganisation of the Milk Supply has recently been issued. Only commercial organisation is considered, though measures against the spread of disease are recommended: these involve the appointment of fresh veterinary inspectors, doubtless with power to order the slaughter of infected animals. Hitherto, the Ministry of Agriculture, unfortunately, has had only one remedy in mind, in dealing with cattle disease—to kill. If it had charge of the community, it would re-Herod Herod and order all children with measles to the destructor—as it does cattle with foot and mouth disease. Preventive vaccine treatment also is at best a palliative. We need to put Pasteur aside and start afresh: having learnt something since his day, the time is come to go forward with constructive ideas of our own. The more we rely on pasteurisation, the less we are likely to go forward with measures to place our milk supply upon a scientific basis.

It is useless to shut the stable door after the steed is stolen, even in dealing with tuberculous cattle. Assuming that the organism were gone from milk, the ever-present far greater danger of the pulmonary form of the disease would remain. It is impossible to kill off the contacts: you can only cure victims at high cost—but how? Definitely, by high feeding!

Why not apply the cure to prevent the disease? The one chance of eliminating tubercular and other zymotic diseases seems to be to feed them out—both from cattle and ourselves. Let us seek to feed both our cattle and ourselves with whole food, rich in all the advitants. We know that there is disease whenever one or more of them is absent. In one region in New Zealand the animals suffer from a recognised deficiency in iodine: in another, from lack of iron. Ours often suffer from want of available iron; in sandstone regions especially the effect of a deficiency of lime and perhaps phosphate is particularly noticeable in the poor development of the horns; calcium is undoubtedly lacking over large areas. Australian and South African soils are known to be greatly deficient, particularly in phosphate, potash and lime. The produce from these countries must often be deficient in quality, on this account.

Proof has been obtained, from numberless experiments on animals, that health is greatly influenced by feeding and that properly fed animals are little if at all subject to bacterial infection. Minor deficiencies may not be easily followed up but, in the long run, their effect may be deep seated. The experiments made with pasteurised milk are all suspect, if only on this account; valid results cannot be obtained with children. Just as milk has been taken to be worthy to be called milk, if only it came from a cow, even from a tuberculous animal, after pasteurisation: so grass was long taken to be grass, if only a cow would eat it; only when it came to fattening animals, was a distinction made. The most important of all cereals, grass has been the least studied: no imagination has been put into the foundations of milk. The Rothamsted plots, however valuable botanically, have taught nothing of grass as a fodder crop. All we know is that grass needs to be treated as well as wheat. Not until the War and in Germany was inquiry directed to the use and special value of nitrogenous fertilisers on its growth. The great value of young grass was then brought to the fore.

In the last few years, inquiries into the growth and use of grass have been carried out in various parts of England, for the production of milk, under the direction of Sir Frederick Keeble, formerly professor of botany at Oxford. The results are in part described and discussed in his book "Fertilizers and Food Production on Arable and Grass Land", a work of great interest, nothing short of a revelation of grass.

One of the most significant results is that obtained last year by the winter feeding of cows with grass, cut young in the summer and forthwith rapidly dried, the grass being taken from pasture fully fertilised with minerals and also with an ammonia salt. Comparison was made with a grass from an adjoining pasture to which no nitrogenous manure had been applied, only minerals. The milk from the cows fed on the 'nitrogenous grass' gave a butter of full summer value in appearance and character; the butter from 'minerals only' was but slightly better than the poor product ordinarily obtained from stall-fed cattle. The result is as striking as that shown at Rothamsted on the celebrated Broadbalk Field, on the two plots, both fully dressed each year with minerals, one or the other only receiving nitrogenous fertiliser each year. Without nitrogen, the crop each year goes down nearly to the level of the nearby permanently unmanured plot.

During last winter, I was able to initiate an experiment with young boys, with the object of determining whether milk, produced with the aid of such summer-cut dried grass, be of special food value compared with the ordinarily 'stall-fed' milk. It is too early to pronounce upon the result but I have been astounded at the way in which the cattle fed upon the dried grass are 'swelling wisibly', like 'the Fat Boy', in comparison with their neighbours. The carotene content of the milk is at a high level. Who shall say what other components may not be equally affected? It is impossible to believe that improvement is in one necessary component only.

With such evidence before us, the way is clear: selfishly, to care for our cattle as much as we care for ourselves: in fact, through them really to care for ourselves, particularly for our children. Housing is of no importance compared with proper feeding.

The supreme value of milk is beyond all question—particularly to the pregnant mother, to the child from the moment of conception, throughout infancy and early youth. Our task now is to make the general supply of such quality that it may serve as a defence against all disease arising in any way from a lowered vitality in ourselves or in farm animals generally from imperfect feeding.

Our cry should be not merely: 'Back to the Land' but 'Honour the Land', by raising its fertility to its fullest extent and enjoying the fruits thereof.

The Indian Institute of Science, Bangalore

THE retirement of Dr. M. O. Forster last month from the directorship of the Indian Institute of Science, Bangalore, after ten years service, and the appointment of Sir C. V. Raman to succeed him, afford an appropriate opportunity to give a general account of this remarkable Institute and its work. In recent years the number of workers in the various departments has greatly increased, and many of the researches carried out by them are of high scientific value, while others have a direct bearing upon the development of the country's natural resources and industrial expansion. There are four scientific departments in the Institute, concerned respectively with general chemistry, organic chemistry, biochemistry and electrical technology, and the range of investigations carried on in each of them is very wide.

Dr. Forster himself is to be congratulated upon the continued progress of the Institute during his directorship and the maintenance of the object for which it was established, namely, to promote original investigations and their use for the benefit of India. His services to the cause of higher scientific education and research in India are widely known and highly appreciated. A remarkable testimony to the regard in which he is held at Bangalore, and a tribute of gratitude from the staff and students of the Institute, were afforded by a large and distinguished company which assembled at the Institute on March 14 to express regret at his departure and convey the best wishes to him and Mrs. Forster. Dr. Forster was presented with an address and a silver casket of exquisite workmanship, and Sir Mirza Ismail, Prime Minister of Mysore, who presided, referred in glowing terms to his zeal and devotion to the Institute. In the course of his speech, Sir Mirza said: "Dr. and Mrs. Forster have come to love this State as much as we do. They have identified themselves with us completely. I need not tell them, for I am sure they know it well enough, that their decision to continue to live amongst us, after retirement, is a source of the utmost gratification to their friends and even to those who are not privileged to know them personally. We feel that we shall be enriched by their presence in our midst. . . ." As Dr. Forster is retiring to the beautiful garden city of Mysore, which is only a couple of hours journey from Bangalore, he will be able to continue in touch with the Institute and its activities.

The Institute originated in the munificence and foresight of Mr. Jamsetji Nusserwanji Tata who, about the year 1896, proposed to place in trust Bombay properties with a capital value of Rs. 30 lakhs (£225,000) to endow a research institute for India. During the development of a scheme for implementing this benefaction, the Government of Mysore allocated 371 acres of suitable property about three miles from the outskirts of Bangalore, contributed Rs. 5 lakhs (£37,500) towards the buildings and promised a subsidy of Rs. 50,000 (£3,750) per annum without limit of time: while the Government of India agreed to make an annual grant of Rs. 1·5 lakhs (£11,250).

On the death of Mr. J. N. Tata, his two sons, the late Sir Dorabji and Sir Ruttonji Tata, announced their intention of giving effect to the wishes of Mr. J. N. Tata, and transferred the Bombay properties to the Treasurer of Charitable Endowments. The vesting order having been signed in May 1909, the Council appointed thereunder authorised the construction and equipment of the buildings already planned by Dr. M. W. Travers, who had been appointed director in August, 1906. The first students were admitted to the departments of general chemistry, applied chemistry and electrical technology in July 1911, the department of organic chemistry being opened in September of the same year.

It was hoped by Sir Dorabji Tata that the Institute would become an all-India institution, and this intention is to some extent realised by the students in it being drawn from all parts of the sub-continent, though for geographical reasons those from Mysore and Madras predominate. On the financial side, however, it cannot be said that the support to the Institute is of an all-India character. Excepting Mysore and Hyderabad, which have uniformly and generously supported the Institute, contributions from other States and Provinces have been altogether disproportionate to the benefits received by their students. Bombay has approximately the same number of students in the Institute as Mysore and Madras, yet it contributes nothing to the finances. The absence of support from Bombay and Bengal is much to be regretted, for it means that other regions are influenced by it and neglect to afford the aid which would make the revenue of the Institute an all-India responsibility.

The following analysis of applications and admissions for the five years 1926–30 shows the geographical distribution, and the considerable excess of applications over admissions from all parts of the country:

	Mysore	Madras	Bombay	Bengal	Rest of India
Applications ..	151	239	244	72	148
Admissions ..	73	88	91	26	51

It was pointed out in an article in *Current Science* of October last that those responsible for developing the resources of the Institute, while placing in the foreground the requirement to impart advanced knowledge, and instruct in the methods of research, have consistently kept in mind any possible bearing which the results may have on the inception of new industries and the improvement of existing ones. Ample evidence of this recurs each year in the appendix to the Council's annual report, showing in abridged form the current subjects of investigation; but although the technological application of the work at the Institute has been wide, and in several cases valuable, there is doubtless room for expansion in this field.

One example of an economic application latterly engaging the attention of the Institute is the systematic inquiry into the cause of spike-disease in sandal. This has now continued during the past five years in co-operation with the Government of Madras and the Coorg Commission, the results being summarised in periodical reports published separately from the *Journal* of the Institute. The latter publication contains a description of the various inquiries, academic and economic, which have been pursued in the laboratories, and in the past fifteen years has comprised about two hundred issues. The range of subjects is wide, and includes many that might be turned to an industrial utilisation of principles or materials. This aspect of the work is reflected in the fact that the major proportion of the Institute's former students have been absorbed into non-academic occupations, particularly in the field of electrical technology.

An estimate of the factors contributing to the growth of the Institute may properly include the following considerations. The original organisation was planned by Dr. M. W. Travers, who served as director from 1906 until 1914, being succeeded in the following year by Sir Alfred Bourne until 1921. On Dr. Travers leaving India after constituting the chemistry laboratories, Prof. J. J. Sudborough became head of the departments of general and organic chemistry, terminating in 1925 his fourteen years' association with the Institute, and having developed a highly efficient department of organic chemistry dealing principally with indigenous natural products. He was ably followed by Prof. J. L. Simonsen, who remained only two years and is now professor of chemistry in the University College of North Wales, Bangor. In 1916, Prof. H. E. Watson, who had rendered excellent service as assistant professor of general and inorganic chemistry since 1910, was appointed professor and is now head of that department, which he has raised to a very high level. On retirement of the late Prof. Rudolf from the chair of applied chemistry in 1914, the duties of that office were assumed in 1916 by Prof. G. J. Fowler, whose reputation in the field of chemical bacteriology led the Council in 1921 to convert the chair into that of biochemistry: this branch he developed in several directions advantageous to India until 1924, when Prof. R. V. Norris was appointed and remained until 1929, making valuable contributions to its activities. Since August of that year Prof. V. Subrahmanyan has been in charge.

Dr. Alfred Hay (who died in April 1932) was appointed as the first professor of electrical technology in January 1908, retiring at the end of 1922. During his fifteen years' tenure he organised an admirable system of training by which engineering graduates of Indian universities are fitted to assume positions of responsibility as electrical engineers. His successor, Prof. J. K. Catterson-Smith (1923–1930), now professor of electrical engineering at King's College, London, greatly extended the premises and equipment of the department, and established a section of electrical communication engineering designed to meet the rapidly expanding interest in wireless telegraphy and telephony. He also founded the Institute Engineering Society, and a journal entitled *Electrotechnics*. In 1931 he was succeeded by Prof. F. N. Mowdawalla.

The *Journal of the Indian Institute of Science* describes the research work issuing from the laboratories, and embraces about two hundred original communications. A preliminary account of these is usually presented at the Indian Science Congress, which has received warm support from the Council by deputations of many students and members of the teaching staff to attend the annual meetings.

An important auxiliary to the work of the departments is the Library, which has been maintained in a state of increasing efficiency by Mr. K. Amrita Row. The library contains 21,000 volumes, principally research journals, and is the best of its kind in India. Research students at Bangalore have thus available for reference the published results of investigations carried on almost anywhere in the world. It is easy to understand, however, that notwithstanding the facilities which the Institute affords for advanced study and research, many students in universities in other parts of India hesitate to undertake post-graduate training there. Even if such an Institute were established in Great Britain, where the distances are not of the same continental order, it may be doubted if it would attract so many science graduates taking courses of advanced study and training for research as are now at Bangalore. Since the Institute was founded there has been a notable increase in the amount of research work carried on in many of the Indian universities, and there is a natural tendency for each such institution to retain its most promising research students instead of letting them go elsewhere.

This and other difficulties in the way of expansion were surveyed by a committee of inquiry, of which Sir William Pope was chairman, appointed in 1921, and helpful suggestions for overcoming them were made in the report of the committee published in the following year. Dr. Forster was appointed director of the Institute shortly after the publication of the report, as a scientific man of eminence with proved administrative capacity, and he has in every way justified his appointment. The committee contemplated the institution of a department of physics as a link between existing activities in physical chemistry and electrical technology, but sufficient financial support has not been afforded to carry out this recommendation. It may be hoped that the new director, Sir Venkata Raman, will by his enthusiasm and untiring energy be able to increase the financial resources sufficiently to establish a new department of physics on a scale worthy of the Institute and of the high expectations of its founder.

Trevithick Centenary Commemorations

During the past week, many tributes have been paid to the memory of Trevithick, the great Cornish inventor and engineer. On April 24 Prof. C. E. Inglis delivered the memorial lecture, at the invitation of the Trevithick Centenary Commemoration Committee, in the theatre of the Institution of Civil Engineers, by kind permission of the council. Sir Murdoch MacDonald, the president of the Institution and the chairman of the Committee, was in the chair.

In beginning his lecture, which is being published in full, with illustrations, in this week's *Engineer*, Prof. Inglis said that when Trevithick died on April 22, 1833, no obituary notices proclaimed that the nation had lost a mechanical genius of the first order of magnitude, and his memory passed into an oblivion which for many years was almost complete. But the greatness of the man, and the impetus he had given to engineering science, was such that his fame could not suffer permanent eclipse. Slowly, but with an ever-increasing luminosity, his genius shone forth, and with the passage of time he seems to rise higher and yet higher above his contemporaries.

Fifty years ago, the name of Richard Trevithick had won an honoured position throughout the engineering world, and now posterity, more discerning than his own generation, deems him not unworthy to be enthroned alongside and on the same exalted plane with his predecessor and one-time rival, the illustrious James Watt.

Trevithick was born at the foot of Carn Brea in the parish of Illogan not far from Camborne on April 13, 1771. Up to about the age of twenty-six years, he was connected with Cornish mining engineering and was familiar with all sides of engineering practice. A man of fine physique, forceful, energetic, self-confident, decisive and independent, he was yet of a kindly, generous disposition and though when goaded by opposition he would flare out, he cherished no animosities and there was a singular absence of anything approaching meanness in his character. The overwhelming vitality and driving force of the man, said Prof. Inglis, is strikingly portrayed in the bronze statue erected in Camborne last year.

Trevithick's great work began with his experiments with steam-driven locomotive models in 1797, and from then until in 1816 he left England for the Peruvian mines, was the period when his constructive genius flared forth with a brilliance which was almost continuous. To those years belonged his construction of the Camborne steam road carriage of 1801, his great patent of 1802 for stationary and locomotive high-pressure engines, his London steam road carriage of 1803, his historic rail locomotive, which he built at Penydarren in South Wales in 1804, his London rail locomotive of 1808, his application of steam engines to pumping, winding, dredging and agriculture, his invention of the Cornish boiler, his attempt to drive a tunnel beneath the Thames between Rotherhithe and Limehouse, and his patents for iron ships, iron docks and iron tanks. During the years 1797–1816 he was, in Prof. Inglis's words, "a veritable volcano of inventions". Some of these, because they ante-dated engineering progress by many years, failed to come to fruition, but others, notably the high-pressure semi-portable steam engine, gave an impetus to mechanical science which gathered momentum with the passage of time, and for which his successors mainly reaped the honour and financial reward.

One of Trevithick's inventions of this time was the water-pressure pumping engine, and speaking of a large engine of this type erected in Derbyshire, Prof. Inglis remarked: "This simple and powerful type of engine was verily the mechanical embodiment of its creator's mental and physical characteristics, and Trevithick's creations invariably inherited his own personal attributes—strength and exuberance of energy almost amounting to rashness." In comparison with Trevithick, Watt was a timorous spirit; steam in his mental vision was merely an agent for forming a vacuum, and the potentialities of danger he envisaged from the use of high-pressure steam outweighed any possible advantages which could be gained thereby. Trevithick, on the other hand, never counted that particular cost; he never permitted potentialities of danger to obscure his horizon, and it was this entire absence of fear which, perhaps more than any other mental characteristic, impelled him forward to win imperishable renown as the originator of the high-pressure engine.

Prof. Inglis's study was naturally based on the record of Trevithick as given in the biography published by his son Francis in 1872, and unfortunately he was not able to throw much new light on the actual construction of the engines through which Trevithick is known as the 'father of the locomotive', but his lecture contained many notable passages concerning the man himself.

The actual centenary celebrations began on Saturday afternoon, April 22, at Camborne by a demonstration. This was followed on Sunday forenoon by memorial services in Tregajorran Methodist Chapel, which stands on the site of Trevithick's birthplace, and in Dartford Parish Church, in which is a bronze tablet recording Trevithick's burial in the churchyard of St. Edmund, King and Martyr. Reference was also made to the centenary at evensong in Westminster Abbey by the Archdeacon of Westminster, the Ven. V. F. Storr, and after this service, the Memorial Committee placed a wreath beneath the Trevithick memorial window in the north aisle.

The service at Dartford Parish Church was attended by many members of the Urban District Council, representatives of many local associations and engineering societies and by the staff and employees of Messrs. J. and E. Hall, Ltd., in whose works Trevithick's last days were spent. The service was conducted by the vicar, the Rev. E. Mitchell, the sermon was preached by the Right Rev. the Lord Bishop of Rochester, and after the service an address was given by Mr. L. St. L. Pendred and wreaths were placed on the memorial tablet.

In concluding an address of singular eloquence, Mr. Pendred said: "I could speak to you of Trevithick's inventions; of his locomotives, his steam boats, his pumps, his boilers, his tunnel under the Thames. But what would it avail? You may read of these things if you will. They are now of no account. The tide of invention has swept over them. Precious and dear to the memory, but all sunken; not reclaimable, not useful any more:

> 'Wedges of gold, great anchors, heaps of pearls,
> Inestimable stones, unvalued jewels,
> All scattered in the bottom of the sea.'

"No inventor will turn to them for inspiration. Dead things. Drowned things. Swept over by the vast flood of invention which broke all barriers soon after Trevithick had gone to rest, and still sweeps onwards. You may see them in the Museum now. Toys; antiques; quaint relics. Valueless things . . . And yet, not valueless if they bring back the gift of Wonder to an age that has ceased to be surprised at anything. And if we can only wonder, we shall pay the greatest tribute of our praise to Trevithick. We shall wonder how a man with so little knowledge, so few opportunities of learning, such poor means of achieving, yet wrought from his brain things that no one else could think of, could *make*. It is not enough to think, one must *do* too. There are always some who will rob every inventor of his honour by proving that others had thought of the same thing before him. Thinking is not enough; it is the men who hammer their thoughts into realities that matter to the world. That was the way of Trevithick, the Cornishman; that is why we honour his name to-day."

Obituary

PROF. J. MILLAR THOMSON, F.R.S.

JOHN MILLAR THOMSON was born in 1849 in the precincts of the old college of Glasgow, where his father, Prof. Allen Thomson, was professor of anatomy. John Millar Thomson's family has had a long connexion with the University of Glasgow, dating from 1761, at which time his great-grandfather, John Millar, was professor of law. Other members of the family afterwards held chairs in mathematics, philosophy, medicine and anatomy, pathology and military surgery in one or other of the Scottish universities.

John Millar Thomson was an only child and was brought up in very close companionship with his father, with the result that he was from early boyhood constantly in contact with notable people in academic circles, especially as his father was one of fourteen professors all living in the old college. As a boy of thirteen years of age he travelled with his father in France and Germany, visiting a number of his father's friends. They remained for some time in Würzburg with Allen Thomson's great friend, Kölliker.

During the time when Prof. Allen Thomson was going into the plans of laboratories and lecture-rooms in the new University buildings at Glasgow, John Millar Thomson accompanied his father on several occasions where, as a boy, he could be helpful in such simple ways as 'holding the tape' and in taking down notes. This started an interest in architectural matters which he retained all his life. In discussing laboratories with him when he was at King's College, I have lively recollections of his sitting down to make plans, and of his saying, as he brought his scales and ivory rule out of his pocket, "These are the very ones with which my old father drew out his plans when I was a boy". His skill as an architect was such that when he drew out plans for a house for one of his cousins, these were accepted by the builders as complete, and were worked to by them.

Educated at the High School and the University of Glasgow, Millar Thomson entered the faculty of medicine after having first taken the usual curriculum in arts. He soon came to the conclusion, however, that he did not wish to continue a medical training. On the advice of Prof. Thomas Anderson and Prof. Lyon Playfair, he took up the study of chemistry. Naturally, from his early associations with so many professors, his ambition was to enter academic life. He worked as a student in Prof. Anderson's laboratory from 1866 until 1871, being appointed assistant to Prof. Anderson in 1869. In 1868 he came to London to see Prof. W. A. Miller and Prof. C. L. Bloxam with regard to a demonstratorship in chemistry at King's College, London, vacant owing to the transference of his friend J. T. Bottomley to the Physical Department of King's College. I remember his telling me about that interview and saying that, after it, he came to the conclusion that he was too young for the post. He returned, therefore, to Glasgow until, on the death of Prof. Miller in 1870, Prof. Bloxam, who succeeded to the chair of chemistry in King's College, sent for him and offered him a position of assistant demonstrator, which he took up early in 1871. Walter N. Hartley at the same time was appointed senior demonstrator. At that time the assistant demonstrator did not lecture, but Hartley became seriously ill shortly after his appointment, and John Millar Thomson took over the whole of the senior demonstrator's work in both the day and evening-class departments. Bloxam told me, in later years, of the great success of John Millar Thomson's lectures and of his organisation of the practical classes given into his charge.

In 1879, Hartley was appointed professor at the College of Science, Dublin, and Millar Thomson became senior demonstrator in his place. I attended his lectures in that year, and I can recall now the ease with which they could be followed, the clearness of his exposition, and the wealth of experiment with which the lectures were illustrated. His lectures were always interesting and often experiments difficult to carry out were shown by him with brilliant success, but he never allowed applause in College lectures. One other thing I can recall very clearly, namely, there was no chance of being visibly inattentive; still less was there any opening for levity or other form of disturbance. This was a tribute not only to his power of holding an audience, but also to his personality: one felt that 'fooling' was quite out of place. But strict and dignified as he was in the work of the College, both then and throughout his career he gained, in addition to the high respect of his students, their lasting affection.

From 1880 until 1887, in addition to his work at King's College, Millar Thomson gave lectures in chemistry at Queen's College, Harley Street, and was given the title of professor of chemistry in that College. It was during this time, and before he took the responsibility of the headship of the Chemical Department at King's College, that he carried out his investigations in connexion with crystallisation and supersaturated solutions, and also on a number of other subjects, for example, the composition and properties of building stones, in continuation of some work which he had done under Prof. Anderson at Glasgow.

Although he was much occupied with his own teaching and experimental work, he was a man with such strong general sympathies that he could not avoid being pressed to take an active and guiding part in practically all the College functions and functions organised by the students' societies. The Dramatic Society in particular owed much to him. He possessed remarkable dramatic talents and was truly a fine actor. This did not appear in his lectures, either at the College or at the many public lectures which he gave; into these he threw all his earnestness. It did, however, give him a singular power of expressing the wishes and desires of others when welcoming a new colleague, bidding good-bye to a retiring colleague, or speaking at functions such as College dinners or public dinners. I always felt, when John Millar Thomson spoke on such occasions, that in virtue of his personality, his manner, and his simple but effective elocution, he set the tone of the whole function on a high level. It was typical of him to say the right thing whenever he was called upon to speak, even at a moment's notice.

I must not omit some reference to his activities in photography, in which he had a life-long interest; for some time in his earlier days he taught the principles and practice of photography to the engineering students of the College.

The individual character and ability which he had shown, and the influence which he had exerted in promoting the highest interests of the College in these earlier posts, were emphasised when Millar Thomson became head of the Chemical Department at King's College. It was natural, therefore, that when the post of vice-principal became vacant in 1905 on the resignation of Prof. W. Grylls Adams, it was the unanimous desire of his colleagues that John Millar Thomson should be invited to take over the additional duties of vice-principal. He accepted, and represented the College on many important occasions. I have often heard from those who were present on such occasions how impressed they were with the charm, power and highmindedness of the man.

In notices of him in other places, his public work in connexion with the Chemical Society, the Institute of Chemistry and the University of London, has been described. I have endeavoured here to give some impression of the man himself. My opportunities for knowing him intimately were many, for I saw a very great deal of him not only in College but also in his private life.

I should not like to conclude without recalling Mrs. John Millar Thomson, the youngest daughter of Dr. Charles Arthur Aikin, a grand-niece of Miss Lucy Aikin, and a grand-niece of Mr. Arthur Aikin (who was secretary of the Royal Society of Arts from 1817 until 1839): she was also a great grand-niece of Mrs. Barbauld. I have often heard John Millar Thomson say how much he owed to the sympathy and ability of his wife. I myself was frequently present in their home, and when we were discussing College matters or the subject of a lecture, he would often turn to her for criticism and suggestions connected with decisions which he had made, and always with benefit.

John Millar Thomson was a remarkable man, of great ability, earnestness of purpose, and commanding influence, combined with a fine sense of humour and a great power of sympathy. He would have been a smaller man if he had realised how great a personality he really was.

HERBERT JACKSON.

THE death is announced of Mr. Walter E. Roth, which took place on April 5 after an operation at Demerara. Mr. Roth was a brother of the late Mr. H. Ling Roth, curator of the Bankfield Museum, Halifax. For many years before proceeding to British Guiana, Mr. Roth was Protector of Aborigines, Queensland, Australia. He was the author of "Ethnological Studies among the North-West Central Queensland Aborigines" (1897) and of a number of monographs on various aspects of the culture of the Queensland aborigines which appeared as official bulletins. He also wrote a number of papers, mostly technological, on the culture of the Indians of British Guiana which appeared in the *Journal of the Royal Anthropological Institute*, the reports of the Bureau of American Ethnology and elsewhere.

News and Views

Jews in Germany

THE political significance of Nazi revolutionary supremacy under Herr Hitler in Germany is outside our field; but the treatment of the Jewish learned and professional classes stands condemned in the eyes of the intellectual world. It is a relapse to the crass repression of the Germany of Heine's day and the *Judenhetze* of Prussia fifty years ago. An outstanding case is the resignation by Prof. James Franck, Nobel prizeman with G. Hertz for physics in 1925, of his chair in experimental physics in the University of Göttingen. Prof. Franck, it is said, probably would have been spared the forced retirement now operative against Jewish officials, including university professors; but he feels that Germans of Jewish descent are being treated as foreigners and foes of the Fatherland, and asks to be released from his office. Prof. Franck served with distinction during the War and received the Iron Cross of the First Class. His action follows fittingly on the retirement of Prof. A. Einstein from Germany, and is the logical, indeed the only, reply for a man of his standing to the acts by which Jews are being excluded from the liberal professions and debarred from the universities. This is the achievement of a movement which, ever since the War, has sought to mould the German people to one pan-Teutonic pattern—in accord with neither the facts nor the conclusions of ethnology. In the denial of a part in Germanic culture to any element alleged to be foreign, Jews, liberals and socialists are to be treated alike; but Jews have suffered most.

THE Jewish people need no one to hold a brief on their behalf. The contribution of the Jews to the growth of civilisation in the Western world speaks for itself. There were Jews in Germany in Roman times, and wherever they were found in medieval Europe, in spite of, or perhaps because of, their disabilities, they were laying the foundations upon which the modern system of finance and commerce was built up. In Italy as bankers, they rivalled the great houses of Lombardy. In the liberal arts, the preservation of much of classical literature and philosophy was due to them. In the later Middle Ages they were largely responsible for the reputation of Spain as a centre of intellectual and scientific development. In the middle of the eighteenth century the revival of Jewish learning, which had Mendelssohn for its inspiration and leader, paved the way for the Jewish people to take its place in the intellectual life of the respective countries of their adoption as their disabilities were gradually removed, so that Bunsen could say that, in the German universities of his day, the greater number of the principal professors were Jews. Everywhere the Jews have won to preeminence in literature, in the arts, especially music, and the drama. Even if it were not admitted that the Jews had contributed to Germanic culture—a contention which could not be accepted without argument—in the world of learning and science it is to men such as Oppert, the classical scholar, Benfey, the Orientalist, and Heinrich Hertz, the physicist, to take three names only, selected almost at random, that she owes her international standing, just as much as to any of her sons of purest German stock.

William Morgan, F.R.S., 1750–1833

WILLIAM MORGAN, who died on May 2, 1833, was the son of a doctor at Bridgend and studied medicine in London, but he failed to make headway after his father's death. He returned to London, where his uncle, Richard Price, found him work with the first life assurance company to grant assurances for the whole of life at a level premium depending on the age when the assurance was effected. This new venture gave Morgan his opportunity. He studied mathematics, applied them to life contingencies and produced, in 1779, his "Doctrine of Annuities and Assurances". He followed this with a series of five papers to the Royal Society in which, for the first time, solutions were given of complicated survivorship probabilities in terms that enabled a computer to use actual mortality statistics instead of an arbitrary law of mortality such as de Moivre's. He was given the Copley Medal in 1789 and his fellowship of the Royal Society in the following year. Morgan did still more important scientific work in connexion with his business, where he worked out the proper reserves that should be kept by a life assurance company and studied the difficult problems of surplus and bonus distribution so skilfully that he evolved a fair method for the particular scale of premium—the general problem still gives difficulty and is widely discussed even now. Morgan also studied the mortality experience of the persons insured, and his manuscript volume on the subject, from which he gave abridged tables in his published work, was the first investigation of the kind. Morgan published some tracts on public finance, wrote a life of Price and edited his works, contributed articles to Rees' "Cyclopedia", etc., and, in earlier days, displayed an interest in electricity and heat. His great achievement was that, in effect, he started the profession of 'actuary' and a new science which would nowadays be called actuarial science, and he proved that life assurance was a practical possibility and not merely an interesting theory.

Dr. William Babington, F.R.S., *1756–1833*

ON April 30 occurs the centenary of the death of Dr. William Babington, one of the founders of the Geological Society of London, who during his life gained the respect and admiration of all with whom he had come in contact, both by his skill as a physician and by the elevation of his character. Born in Ireland in 1756, at the age of twenty-one he became an assistant surgeon at the Haslar Naval Hospital, and four years later was appointed apothecary to Guy's Hospital, London, of which for some years he was also the physician. Though he made no notable contribution to science, he wrote several acceptable works on chemistry and mineralogy and it was at his house that in 1807 the gathering took place which led to the formation of the Geological Society, the first president of which was that "staunch geological Tory" George Bellas Greenough. Babington himself served as president in 1822 of the Society he had assisted to found. He was also one of the founders of the Hunterian Society. Described by Geikie as "a kindly, bland and courteous veteran", one of his last public actions before he fell a victim to an epidemic of influenza was to preside over the Priestley centenary celebrations. It was said that history does not recall a physician more loved and respected than Babington, and it was this wide-spread admiration for his character which led to the erection of his statue in St. Paul's Cathedral. The statue is a noble piece of work by Behnes. At his death, Babington was buried in St. Mary Aldermanbury in the City. He left several children and one of his daughters became the wife of Dr. Richard Bright, the discoverer of 'Bright's disease'.

Eradication of Prickly Pear in Australia

STRIKING success continues to attend the efforts to eradicate prickly pear (*Opuntia* spp.) in Queensland and northern New South Wales, mainly through the introduction of *Cactoblastis cactorum*. By the end of 1930, some 3,000,000,000 eggs had been distributed throughout the length and breadth of the sixty million acres infested and by the end of 1931 the insect existed on practically every acre. To-day probably 80 per cent of the dense primary pear in Queensland has been destroyed, while in New South Wales the figure is 50–60 per cent if one excludes the Hunter Valley and Camden districts where climatic and soil factors are delaying, but not preventing, the progress of *Cactoblastis*. Queensland is energetically pushing a scheme of development of reclaimed land and already 1,515,000 acres have been re-selected for mixed farming purposes and 1,701,000 for grazing. Unfortunately, the sight of miles of dead and rotting cactus tends to create the impression in political circles that the problem is solved and that further expenditure upon intensive research work is not needed.

SUCH views are dangerous and quite unjustified. Re-growth, owing to incomplete destruction of butts and roots, is a problem which grows in seriousness as the old pear, supporting an insect population ready to attack new shoots, disappears. It will be unwise to leave the control of re-growth to *Cactoblastis* alone. Also parasitism, though not yet causing more than 20 per cent loss in any district, and much less in some, requires close watching: and the Hunter Valley area of two to three million acres presents a unique problem in some respects, though *Cactoblastis* is more promising there to-day than it was eighteen months ago. Moreover, though the infestation is almost entirely the vulnerable *O. inermis* and *O. stricta*, it would be unwise to ignore the menace of the tiger-pear (*O. aurautiaca*) now covering some 25,000 acres, and the tree pears (*O. tomentosa* and *O. streptacantha*). *Cactoblastis* destroys the upper growth but not the underground bulb of the former, the recuperative powers of which are very great; while it destroys only the young plants of *O. tomentosa*. Other enemies of these must be sought and entomologists have already been sent to South America to seek parasites of them and allied species.

A Complex Solar Halo

A VERY well-developed solar halo of 22° radius with mock sun ring was observed from places in Kent and Sussex on April 14. An excellent description has been received from Mr. R. C. T. Evans and his son, Dr. C. Evans, 10 Eddington Lane, Herne Bay. The 22° halo was observed at about 12.35 p.m. (B.S.T.), and two "bright patches" proceeding not quite radially from the eastern and western sides, at angular positions corresponding roughly with those of the hour hand of a watch at 9.30 and 2.30 o'clock. Shortly afterwards, these bright patches were observed to form part of a luminous ring which reached northwards to about the position of the pole star (invisible, of course, at the time) but did not cross the region inside the 22° halo. The elevation of the sun must have been nearly 48° at this time and that of the pole star only very slightly greater in this latitude; there seems, therefore, every reason for believing that this ring, which was faint except near the 22° halo, was the mock sun ring, which has the zenith for its centre. The 22° halo showed strong red coloration on the edge nearest to the sun, and a suspicion of blue towards the outside—usual features when this halo is strongly developed. There are two points of particular interest about this display. The haloes were seen from near the centre of a large anticyclone, whereas well-developed haloes are more often seen near the outer margin of a depression or even well within the cyclonic vortex. Further, the description from Herne Bay states that the bright patches near the 22° halo, which formed part of the mock sun ring, showed some red colour at the ends nearest to the sun, which is unusual, and they appeared to lie between the observer and one of several flocculent clouds present in the sky which passed across the eastern bright patch. Optical theory suggests that all parts of the haloes were due to a much more elevated veil of cirriform cloud which, on this occasion, was only dense enough to make the blue of the sky appear pale, and that the flocculent clouds should have lain in front of the haloes.

New Ascent into Stratosphere
